1 Introduction

The Statistical Data and Metadata Exchange (SDMX) initiative (<https://www.sdmx.org>) sets standards that can facilitate the exchange of statistical data and metadata using modern information technology.

The SDMX Technical Specifications are organised into several discrete sections.

The following are published on the SDMX website (<https://www.sdmx.org>):

Section 1 Framework for SDMX Technical Standards – this document providing an introduction to the technical standards.

Section 2 SDMX Information Model - the SDMX information model is a standardised object model for modelling statistical domains centring on the structure of their data and metadata sets, the coding schemes used for classification, and the rules for controlling the exchange of data and metadata between organisations. This document provides a UML specification with supporting narrative.

Section 5 SDMX Registry Specification – an SDMX ‘registry’ acts as a repository for structural metadata and provisioning information, and a registry of data and metadata sources. This document sets out the specification.

Section 6 SDMX Technical Notes – detailed technical guidance for implementors of the SDMX standard.

The following are published on the GitHub repository of the SDMX Standards Technical Working Group (<https://github.com/sdmx-twg>):

sdmx-twg/sdmx-rest – REST API

Technical specifications for the SDMX RESTful web services application programming interfaces (API).

sdmx-twg/sdmx-ml – SDMX-ML

Technical specifications for the XML transmission format including XSD schemas, documentation and samples for data, structure and reference metadata messages.

sdmx-twg/sdmx-json – SDMX-JSON

Technical specifications for the JSON transmission format including documentation, schemas and samples for data, structure and reference metadata messages.

sdmx-twg/sdmx-csv – SDMX-CSV

Technical specifications for the SDMX-CSV transmission format for ‘comma-separated values’ (CSV) data and reference metadata.

The following sections are obsolete:

Section 3 - SDMX-ML - replaced by the sdmx-twg/sdmx-ml GitHub repository

Section 4 - SDMX-EDI

Section 7 - API - replaced by the sdmx-twg/sdmx-rest GitHub repository

49 VTL

50 In July 2020 the SDMX 2.1 specifications were revised to add support for the Validation and
51 Transformation Language (VTL). For 3.0, the VTL specification has been updated to align with
52 changes to the information model and other modifications to the Standard such as the
53 introduction of Semantic Versioning for the versioning of structural metadata artefacts. Section
54 2 (Information Model) sets out details of the ‘Transformation and Expressions’ package for
55 defining and managing VTL 2.0 programs and Section 6 (Technical Notes) provides detailed
56 guidance on implementing and using VTL with SDMX.

57

58 **2 Change History**

59 The 2.0 version of this standard represented a significant increase in scope, and also provided
60 more complete support in those areas covered in the version 1.0 specification. Version 2.0 of
61 this standard is backward-compatible with version 1.0, so that existing implementations can be
62 easily migrated to conformance with version 2.0.

63

64 The 2.1 version of this standard represents a set of changes resulting from several years of
65 implementation experience with the 2.0 standard. The changes do not represent a major
66 increase in scope or functionality, but do correct some bugs, and add functionalities in some
67 cases. Major changes in SDMX-ML include a much stronger alignment of the XML Schemas
68 with the Information Model, to emphasize inheritance and object-oriented features, and
69 increased precision and flexibility in the attachment of metadata reports to specific objects in the
70 SDMX Information Model.

71

72 The 3.0 version incorporates new features, improvements and changes arising from the
73 collective knowledge gained from a decade of operating experience with the 2.1 standard. In
74 pursuit of modernisation and simplification, features considered obsolete have been deprecated
75 – in particular the EDI transmission format, the lesser-used XML data messages and the SOAP
76 web services API. Many areas remain backwardly compatible with 2.1, but there are some
77 breaking changes where the information model has been redesigned to better support practical
78 use case. Structure mapping and reference metadata are examples. The opportunity has been
79 taken to revise the RESTful web services API which is also not backwardly compatible, but
80 benefits from a rationalisation and better organisations of resources, and a much richer data
81 query URL syntax.

82

83 **2.1 Major Changes from 1.0 to 2.0**

84

- 85 • **Reference Metadata:** In addition to describing and specifying data structures and
86 formats (along with related structural metadata), the version 2.0 specification also
87 provides for the exchange of metadata which is distinct from the structural metadata in
88 the 1.0 version. This category includes “reference” metadata (regarding data quality,
89 methodology, and similar types – it can be configured by the user to include whatever
90 concepts require reporting); metadata related to data provisioning (release calendar
91 information, description of the data and metadata provided, etc.); and metadata relevant
92 to the exchange of categorization schemes.
- 93 • **SDMX Registry:** Provision is made in the 2.0 standard for standard communication with
94 registry services, to support a data-sharing model of statistical exchange. These
95 services include registration of data and metadata, querying of registered data and
96 metadata, and subscription/notification.

- **Structural Metadata:** The support for exchange of statistical data and related structural metadata has been expanded. Some support is provided for qualitative data; data cube structures are described; hierarchical code lists are supported; relationships between data structures can be expressed, providing support for extensibility of data structures; and the description of functional dependencies within cubes are supported.

2.2 Major Changes from 2.0 to 2.1

- **Web-Services-Oriented Changes:** Several organizations have been implementing web services applications using SDMX, and these implementations have resulted in several changes to the specifications. Because the nature of SDMX web services could not be anticipated at the time of the original drafting of the specifications, the web services guidelines have been completely re-developed.
- **Presentational Changes:** Much work has gone into using various technologies for the visualization of SDMX data and metadata, and some changes have been proposed as a result, to better leverage this graphical visualization. These changes are largely to leverage the Cross-domain Concepts of the Content Oriented Guidelines.
- **Consistency Issues:** There have been some areas where the draft specifications were inconsistent in minor ways, and these have been addressed.
- **Clarifications in Documentation:** In some cases, it has been identified that the documentation of specific fields within the standard needed clarification and elaboration, and these issues have been addressed.
- **Optimization for XML Technologies:** Implementation has shown that it is possible to better organize the XML schemas for use within common technology development tools which work with XML. These changes are primarily focused on leveraging the object-oriented features of W3C XML Schema to allow for easier processing of SDMX data and metadata.
- **Consistency between the SDMX-ML and the SDMX Information Model:** Certain aspects of the XML schemas and UML model have been more closely aligned, to allow for easier comprehension of the SDMX model.
- **Technical Bugs:** Some minor technical bugs have been identified in the registry interfaces and elsewhere. These bugs have been addressed.
- **Support for Non-Time-Series Data in the Generic Format:** One area which has been extended is the ability to express non-time-series data as part of the generic data message.
- **Simplification of the data structure definition - specific message types:** Both time series (version 2.0 Compact) and non-time series data sets (version 2.0 Cross Sectional) use the same underlying structure for a structure-specific formatted message, which is specific to the Data Structure Definition of the data set.
- **Simplification and better support for the metadata structure:** New use cases have been reported and these are now supported by a re-modelled metadata structure definition.
- **Support for partial item schemes such as a code list:** The concept of a partial (subset) item scheme such as a partial code list for use in exchange scenarios has been introduced.

144 **2.3 Major Changes from 2.1 to 3.0**

145

146 SDMX version 3.0 introduces new features, improvements and changes to the Standard in the
147 following key areas:

148

149 **Information Model**

- 150 • Simplification and improvement of the reference metadata model
- 151 • Support for microdata
- 152 • Support for geospatial data
- 153 • Support for code list extension and discriminated union of code lists
- 154 • Improvements to structure mapping
- 155 • Improvements to code hierarchies for data discovery
- 156 • Improvements to constraints

157

158 **Versioning of Structural Metadata Artefacts**

- 159 • Adoption of the three-number semantic versioning standard for structural metadata
160 artefacts (<https://semver.org>)

161

162 **REST Web Services Application Programming Interface (API)**

- 163 • Change to a single 'structure' resource for structure queries simplifying the REST API
164 specification by reducing the number of resources to five
- 165 • Improvements to data queries
- 166 • Improvements to reference metadata queries
- 167 • Support for structural metadata maintenance using HTTP PUT, POST and DELETE
168 verbs

169

170 **SOAP Web Services API**

- 171 • The SOAP web services API has been deprecated with version 3.0 standardising on
172 REST

173

174 **XML, JSON, CSV and EDI Transmission formats**

- 175 • The SDMX-ML, SDMX-JSON and SDMX-CSV specifications have been extended and
176 modified where needed to support the new features and changes such as reference
177 metadata and microdata
- 178 • Obsolete SDMX-ML data message variants including Generic, Compact, Utility and
179 Cross-sectional have been deprecated standardising on Structure Specific Data as the
180 sole XML format for data exchange
- 181 • The SDMX-EDI transmission format for structures and data has been deprecated
- 182 • The organisation of structures into 'collections' in SDMX-ML and SDMX-JSON
183 structure messages has been flattened and simplified

- 184 • The option to reference structures in SDMX-ML and SDMX-JSON messages using
185 Agency, ID and Version has been deprecated with URN now exclusively used for all
186 non-local referencing purpose

187

188 Several of the changes are 'breaking' meaning that, in specific cases, the version 3.0
189 specification is not backwardly compatible with earlier versions of the Standard.

190 The principle breaking changes are:

- 191 • REST API – The REST API is not backwardly compatible due to modifications to the
192 URLs and query parameters resulting in breaking changes in four of the five main
193 resources.
- 194 • SOAP API – Deprecation of the SOAP API means that existing systems designed to
195 use SOAP will not work with version 3.0 registries.
- 196 • SDMX-ML – SDMX 2.1 and earlier structure, data and metadata XML messages are
197 not valid in version 3.0. Specifically: legacy data messages including Generic, Compact
198 and Utility are no longer supported. The remaining Structure Specific data message
199 has been changed to support new features such as reporting of reference metadata as
200 part of the dataset, Structure messages have a number of breaking changes,
201 principally modification to the information model, removal of the agency-version-id
202 option for referencing artefacts and changes to the way the structures are organised
203 into 'collections' within the message.
- 204 • SDMX-JSON – SDMX 2.1 structure, data and metadata JSON messages are not valid
205 in version 3.0. The data message has been changed to support the improved REST
206 data queries, in particular the ability to retrieve in one operation data from multiple
207 datasets with potentially different Data Structure Definitions. Breaking changes similar
208 to those for the SDMX-ML transmission format have been made to the structure
209 message.
- 210 • SDMX-CSV - The CSV data and reference metadata messages are not backwardly
211 compatible with those under version 2.1 due to changes to the structure of the
212 messages needed to support new features such as the improved REST API data
213 queries.
- 214 • SDMX-EDI – Deprecation of the EDI transmission format means that existing systems
215 designed to send or receive structures or data in EDI will not work with version 3.0
216 registries.
- 217 • Information Model – Several structures have been changed in the version 3.0 model
218 and three removed. For these reasons the version 3.0 model is not directly compatible
219 with version 2.1 or earlier, although conversion of specific artefacts is possible under
220 some circumstances. Loss of information during the conversion process however
221 means that in cases like structure mapping, the conversion is not reversible i.e. it is not
222 possible to recreate the 2.1 structure once it has been converted to the 3.0 model.

223 The SDMX 3.0 Major Changes document provides more information including an analysis of
224 the breaking changes.

225 3 Processes and Business Scope

226 3.1 Process Patterns

227 SDMX identifies three basic process patterns regarding the exchange of statistical data and
228 metadata. These can be described as follows:

229

230

231

232

233

234

1. *Bilateral exchange*: All aspects of the exchange process are agreed between counterparties, including the mechanism for exchange of data and metadata, the formats, the frequency or schedule, and the mode used for communications regarding the exchange. This is perhaps the most common process pattern.

235

236

237

238

239

240

241

242

243

2. *Gateway exchange*: Gateway exchanges are an organized set of bilateral exchanges, in which several data and metadata collecting organizations or individuals agree to exchange the collected information with each other in a single, known format, and according to a single, known process. This pattern has the effect of reducing the burden of managing multiple bilateral exchanges (in data and metadata collection) across the sharing organizations/individuals. This is also a very common process pattern in the statistical area, where communities of institutions agree on ways to gain efficiencies within the scope of their collective responsibilities.

244

245

246

247

248

249

3. *Data-sharing exchange*: Open, freely available data formats and process patterns are known and standard. Thus, any organization or individual can use any counterparty's data and metadata (assuming they are permitted access to it). This model requires no bilateral agreement, but only requires that data and metadata providers and consumers adhere to the standards.

250

251

252

253

254

255

256

257

This document specifies the SDMX standards designed to facilitate exchanges based on any of these process patterns, and shows how SDMX offers advantages in all cases. It is possible to agree bilaterally to use a standard format (such as SDMX-ML or SDMX-JSON); it is possible for data senders in a gateway process to use a standard format for data exchange with each other, or with any data providers who agree to do so; it is possible to agree to use the full set of SDMX standards to support a common data-sharing process of exchange, whether based on an SDMX-conformant registry or some other architecture.

258

259

260

261

262

263

264

265

266

267

The standards specified here specifically support a data-sharing process based on the use of central registry services. Registry services provide visibility into the data and metadata existing within the community, and support the access and use of this data and metadata by providing a set of triggers for automated processing. The data or metadata itself is not stored in a central registry – these services merely provide a useful set of metadata about the data (and additional metadata) in a known location, so that users/applications can easily locate and obtain whatever data and/or metadata is registered. The use of standards for all data, metadata, and the registry services themselves is ubiquitous, permitting a high level of automation within a data-sharing community.

268

269

270

It should be pointed out that these different process models are not mutually exclusive – a single system capable of expressing data and metadata in SDMX-conformant formats could support all three scenarios. Different standards may be applicable to different processes (for

271 example, many registry services interfaces are used only in a data-sharing scenario) but all
272 have a common basis in a shared information model.

273

274 In addition to looking at collection and reporting, it is also important to consider the
275 dissemination of data. Data and metadata – no matter how they are exchanged between
276 counterparties in the process of their development and creation – are all eventually supplied
277 to an end user of some type. Often, this is through specific applications inside of institutions.
278 But more and more frequently, data and metadata are also published on websites in various
279 formats. The dissemination of data and its accompanying metadata on the web is a focus of
280 the SDMX standards. Standards for statistical data and metadata allow improvements in the
281 publication of data – it becomes more easily possible to process a standard format once the
282 data is obtained, and the data and metadata are linked together, making the comprehension
283 and further processing of the data easier.

284

285 In discussions of statistical data, there are many aspects of its dissemination which impact
286 data quality: data discovery, ease of use, and timeliness. SDMX standards provide support
287 for all of these aspects of data dissemination. Standard data formats promote ease of use,
288 and provide links to relevant metadata. The concept of registry services means that data and
289 metadata can more easily be discovered. Timeliness is improved throughout the data
290 lifecycle by increases in efficiency, promoted through the availability of metadata and ease
291 of use.

292

293 It is important to note that SDMX is primarily focused on the *exchange* and *dissemination* of
294 statistical data and metadata. There may also be many uses for the standard model and
295 formats specified here in the context of internal processing of data that are not concerned
296 with the exchange between organizations and users, however. It is felt that a clear, standard
297 formatting of data and metadata for the purposes of exchange and dissemination can also
298 facilitate internal processing by organizations and users, but this is not the focus of the
299 specification.

300 **3.2 SDMX and Process Automation**

301 Statistical data and metadata exchanges employ many different automated processes, but
302 some are of more general interest than others. There are some common information
303 technologies that are nearly ubiquitous within information systems today. SDMX aims to
304 provide standards that are most useful for these automated processes and technologies.

305

306 Briefly, these can be described as:

307

308 1. *Batch Exchange of Data and Metadata:* The transmission of whole or partial
309 databases between counterparties, including incremental updating.

310

311 2. *Provision of Data and Metadata on the Internet:* Internet technology - including its use
312 in private or semi-private TCP/IP networks - is extremely common. This technology
313 includes XML, JSON and REST web services as primary mechanisms for automating
314 data and metadata provision, as well as the more traditional static HTML and
315 database-driven publishing.

316

317 3. *Generic Processes:* While many applications and processes are specific to some set
318 of data and metadata, other types of automated services and processes are designed

319 to handle any type of statistical data and metadata whatsoever. This is particularly
320 true in cases where portal sites and data feeds are made available on the Internet.

321

322 4. *Presentation and Transformation of Data*: In order to make data and metadata useful
323 to consumers, they must support automated processes that transform them into
324 application-specific processing formats, other standard formats, and presentational
325 formats. Although not strictly an aspect of exchange, this type of automated
326 processing represents a set of requirements that must be supported if the information
327 exchange between counterparties is itself to be supported.

328

329 The SDMX standards specified here are designed to support the requirements of all of these
330 automation processes and technologies.

331 **3.3 Statistical Data and Metadata**

332 To avoid confusion about which "data" and "metadata" are the intended content of the SDMX
333 formats specified here, a statement of scope is offered. Statistical "data" are sets of often
334 numeric observations which typically have time associated with them. They are associated
335 with a set of metadata values, representing specific concepts, which act as identifiers and
336 descriptors of the data. These metadata values and concepts can be understood as the
337 named dimensions of a multi-dimensional co-ordinate system, describing what is often called
338 a "cube" of data.

339

340 SDMX identifies a standard technique for modelling, expressing, and understanding the
341 structure of this multi-dimensional "cube", allowing automated processing of data from a
342 variety of sources. This approach is widely applicable across types of data and attempts to
343 provide the simplest and most easily comprehensible technique that will support the
344 exchange of this broad set of data and related metadata.

345

346 The term "metadata" is very broad indeed. A distinction can be made between "structural"
347 metadata – those concepts used in the description and identification of statistical data and
348 metadata – and "reference" metadata – the larger set of concepts that describe and qualify
349 statistical data sets and processing more generally, and which are often associated not with
350 specific observations or series of data, but with entire collections of data or even the
351 institutions which provide that data.

352

353 The SDMX Information Model provides for the structuring not only of data, but also of
354 "reference" metadata. While these reference metadata structures exist independent of the
355 data and its structural metadata, they are often linked. The SDMX Information Model provides
356 for the attachment of reference metadata to any part of the data or structural metadata, as
357 well as for the reporting and exchange of the reference metadata and its structural
358 descriptions. This function of the SDMX standards supports many aspects of data quality
359 initiatives, allowing as it does for the exchange of metadata in its broadest sense, of which
360 quality-related metadata is a major part.

361

362 Metadata are associated not only with data, but also with the process of providing and
363 managing the flow of data. The SDMX Information Model provides for a set of metadata
364 concerned with "data provisioning" – metadata which are useful to those who need to
365 understand the content and form of a data provider's output. Each data provider can describe
366 in standard fashion the content of and dependencies within the data and metadata sets which

367 they produce, and supply information about the scheduling and mechanism by which their
368 data and metadata are provided. This allows for automation of some validation and control
369 functions, as well as supporting management of data reporting.

370

371 SDMX also recognizes the importance of classification schemes in organizing and managing
372 the exchange and dissemination of data and metadata. It is possible to express information
373 about classification schemes and domain categories in SDMX, along with their relationships
374 to data and metadata sets, as well as to categorize other objects in the model.

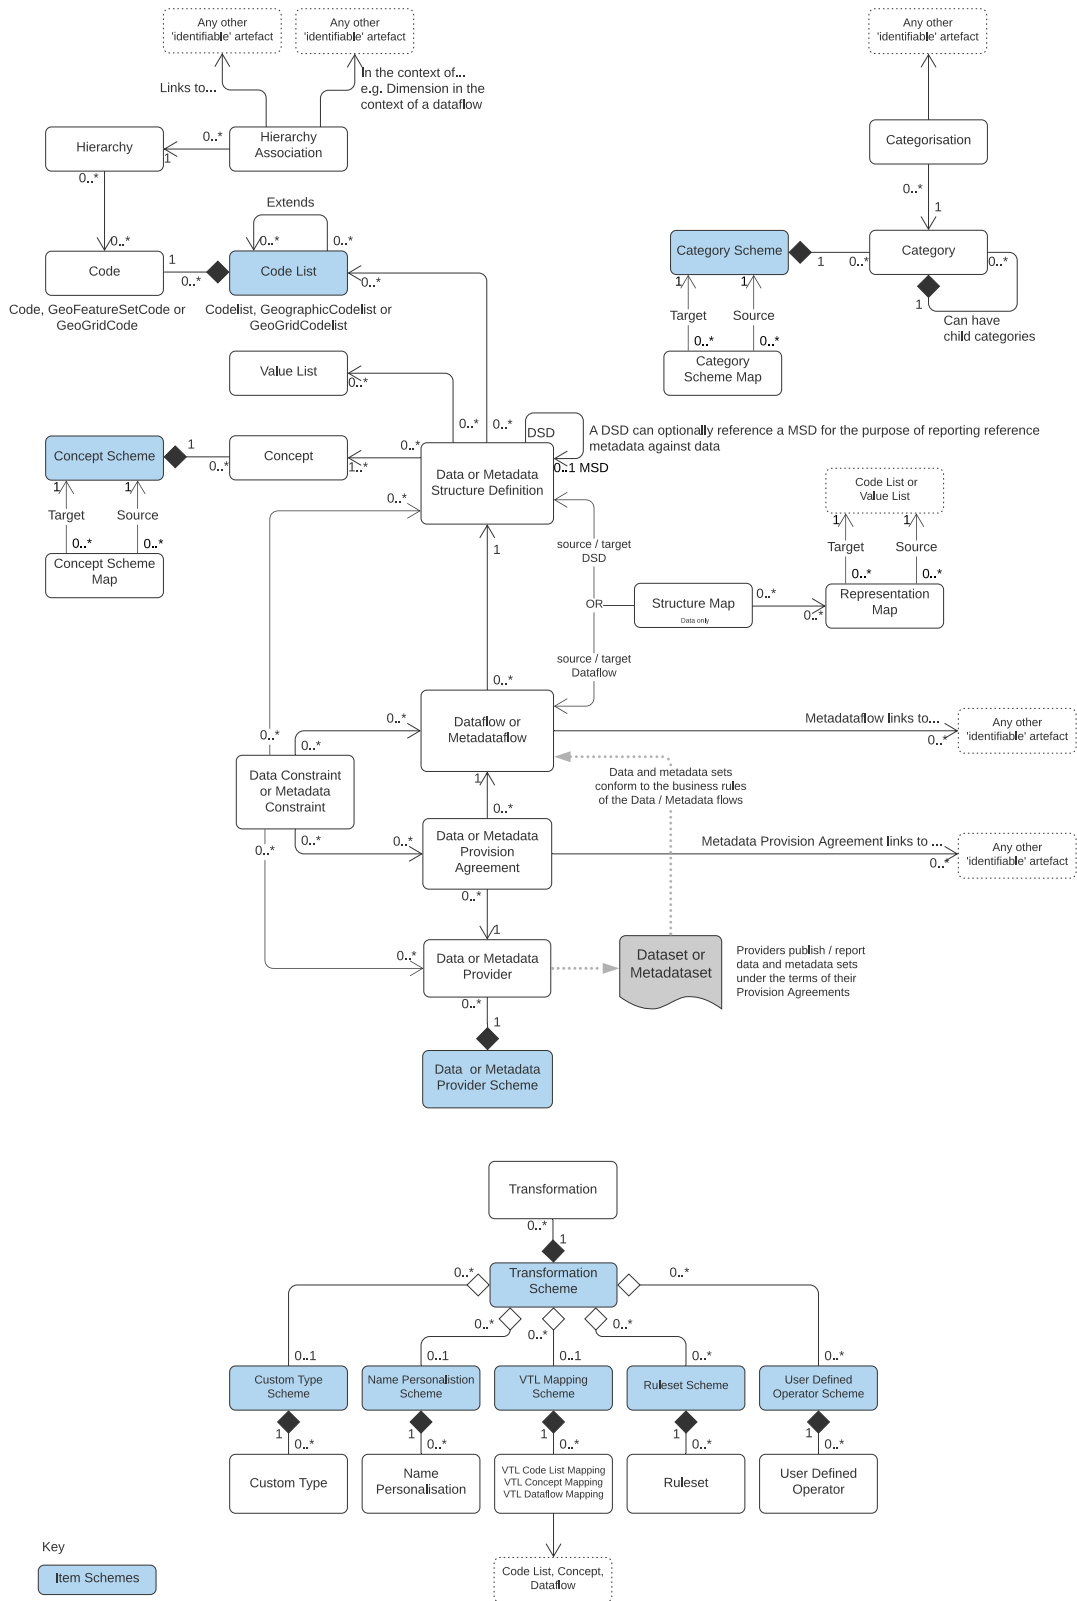

375

376 The SDMX standards offer a common model, a choice of syntax and, for XML, a choice of
377 data formats which support the exchange of any type of statistical data meeting the definition
378 above; several optimized formats are specified based on the specific requirements of each
379 implementation, as described below in the SDMX-ML section.

380

381 The formal objects in the information model are presented schematically in Figure 1, and are
382 discussed in more detail elsewhere in this document.

383

384
385

Figure 1: High Level Schematic of Major Artefacts in the SDMX 3.0 Information Model

386 **3.4 The SDMX View of Statistical Exchange**

387 Version 1.0 of ISO/TS 17369 SDMX covered statistical data sets and the metadata related
388 to the structure of these data sets. This scope was useful in supporting the different models
389 of statistical exchange (bilateral exchange, gateway exchange, and data-sharing) but was
390 not by itself sufficient to support them completely. Versions 2.0 and 2.1 provide a much more
391 complete view of statistical exchange, so that an open data-sharing model can be fully
392 supported, and other models of exchange can be more completely automated. In order to
393 produce technical standards that will support this increased scope, the SDMX Information
394 Model provides a broader set of formal objects which describe the actors, processes, and
395 resources within statistical exchanges.

396

397 It is important to understand the set of formal objects not only in a technical sense, but also
398 in terms of what they represent in the real-world exchange of statistical data and metadata.

399

400 The first version of SDMX provided for data sets - specific statistical data reported according
401 to a specific structure, for a specific time range - and for data structure definitions - the
402 metadata which describes the structure of statistical data sets. These are important objects
403 in statistical exchanges, and are retained and enhanced in the second version of the
404 standards in a backward-compatible form. A related object in statistical exchanges is the
405 "data flow" - this supports the concept of data reporting or dissemination on an ongoing basis.
406 "Data flows" can be understood as data sets which are not bounded by time. Data structures
407 are owned and maintained by agencies - in a similar fashion, data flows are owned by
408 maintenance agencies.

409

410 SDMX allows for the publication of statistical data (and the related structural metadata) but
411 also provided for the standard, systematic representation of reference metadata. In version
412 2.1, reference metadata were reported independent of the statistical data. However, in 3.0
413 reference metadata associated directly with data such as footnotes are reported as attributes
414 of the data set. For other reference metadata, principally that linked to structures like
415 "concepts", SDMX provides reference "metadata sets", "metadata structure definitions", and
416 "metadata flows". These objects are very similar to data sets, data structure definitions, and
417 data flows, but concern reference metadata rather than statistical observations. In the same
418 way that data providers may publish statistical data, they may also publish reference
419 metadata. Metadata structural definitions are maintained by agencies in a fashion similar to
420 the way that agencies maintain data structure definitions, the structural definitions of data
421 sets.

422

423 The structural definitions of both data and reference metadata associate specific statistical
424 concepts with their representations, whether textual, coded, etc. These concepts are taken
425 from a "concept scheme" which is maintained by a specific agency. Concept schemes group
426 a set of concepts, provide their definitions and names, and allow for semantic relationships
427 to be expressed, when some concepts are specializations of others. It is possible for a single
428 concept scheme to be used both for data structures - key families - and for reference
429 metadata structures.

430

431 Inherent in any statistical exchange – and in many dissemination activities – is a concept of
432 "service level agreement", even if this is not formalized or made explicit. SDMX incorporates
433 this idea in objects termed "provision agreements". Data providers may provide data to many
434 different data flows. Data flows may incorporate data coming from more than one data

435 provider. Provision agreements are the objects which tell you which data providers are
436 supplying what data to which data flows. Similarly, metadata provision agreements for
437 metadata flows.

438

439 Provision agreements allow for a variety of information to be made available: the schedule
440 by which statistical data or metadata is reported or published, the specific topics about which
441 data or metadata is reported within the theoretically possible set of data (as described by a
442 data structure definition or reference metadata structure definition), and the time period
443 covered by the statistical data and metadata. This set of information is termed "constraint" in
444 the SDMX Information Model.

445

446 A brief summary of the objects described in the information model includes:

447

448 • **Data Set:** Data is organized into discrete sets, which include particular observations
449 for a specific period of time. A data set can be understood as a collection of similar
450 data, sharing a structure, which covers a fixed period of time.

451 • **Data Structure Definition (DSD, also known as Key Family in Version 2.0):** Each
452 data set has a set of structural metadata. These descriptions are referred to in SDMX
453 as Data Structure Definitions, which include information about how concepts are
454 associated with the measures, dimensions, and attributes of a data "cube," along with
455 information about the representation of data and related identifying and descriptive
456 (structural) metadata. In Version 2.1, the term "Key Family" was replaced by "Data
457 Structure Definition" (DSD) both in XML Schemas and the Information Model. The
458 DSD has been modified in version 3.0 to better support microdata by providing the
459 option to define multiple measures and for attributes and measures to take arrays of
460 values. An optional reference to a Metadata Structure Definition has also been added
461 for describing the reference metadata associated with the data. When reported, these
462 reference metadata are included as part of the dataset.

463 • **Code list:** Code lists enumerate a set of codes to be used in the representation of
464 dimensions, attributes, and other structural parts of SDMX. Codes can be organised
465 into simple hierarchies within a code list, and more complex hierarchies potentially
466 involving multiple code lists using hierarchy and hierarchy association structures.

467 • **Value list:** Value lists introduced in version 3.0 are similar to codelists with the
468 exception that the items do not need to conform to the usual SDMX rules for
469 identifiable objects. That allows the values to include characters such as currency
470 symbols (e.g. ¥) which would otherwise make illegal codes. However, unlike codes,
471 values are not individually identifiable. Value lists find application in concepts and
472 data structures definitions for less structured data and microdata enumerations and
473 can be mapped to other value or code lists using representation maps.

474 • **Organisation Scheme:** Organisations and organisation structure can be defined in
475 an Organisation Scheme. Specific Organisation Schemes exist for Maintenance
476 Agency, Data Provider, Metadata Provider, Data Consumer, and Organisation Unit.

477 • **Category Scheme and Categorisation:** Category schemes are made up of a
478 hierarchy of categories, which in SDMX may include any type of useful classification
479 for the organization of data and metadata. A Categorisation links a category to an
480 identifiable object. In this way sets of objects can be categorised. A statistical subject-
481 matter domain scheme is implemented in SDMX as a Category Scheme.

482 • **Concept Scheme:** A concept scheme is a maintained list of concepts that are used
483 in data structure definitions and metadata structure definitions. There can be many

- 484 such concept schemes. A “core” representation of the concept can be specified (e.g.
485 a core code list, or other representation such as “date”). Note that this core
486 representation can be overridden in the data structure definition or metadata structure
487 definition that uses the concept. Indeed, organisations wishing to remain with version
488 1.0 key family schema specifications will continue to declare the representation in the
489 key family definition.
- 490 • **Metadata Set:** A reference metadata set is a set of information pertaining to an object
491 within the formal SDMX view of statistical exchange: they may describe the
492 maintainers of data or structural definitions; they may describe the schedule on which
493 data is released; they may describe the flow of a single type of data over time; they
494 may describe the quality of data, etc. In SDMX, the creators of reference metadata
495 may take whatever concepts they are concerned with, or obliged to report, and
496 provide a reference metadata set containing that information.
 - 497 • **Metadata Structure Definition:** A reference metadata set also has a set of structural
498 metadata which describes how it is organized. This metadata set identifies what
499 reference metadata concepts are being reported, how these concepts relate to each
500 other (typically as hierarchies), what their presentational structure is, how they may
501 be represented (as free text, as coded values, etc.), and with which formal SDMX
502 object types they are associated.
 - 503 • **Dataflow Definition:** In SDMX, data sets are reported or disseminated according to
504 a data flow definition. The data flow definition identifies the data structure definition
505 and may be associated with one or more subject matter domains via a Categorisation
506 (this facilitates the search for data according to organised category schemes).
507 Constraints, in terms of reporting periodicity or sub set of possible keys that are
508 allowed in a data set, may be attached to the data flow definition.
 - 509 • **Metadataflow Definition:** A metadata flow definition is very similar to a data flow
510 definition, but describes, categorises, and constrains metadata sets.
 - 511 • **Data Provider:** An organization which produces data is termed a data provider.
 - 512 • **Metadata Provider:** An organization which produces reference metadata is termed
513 a metadata provider.
 - 514 • **Provision Agreement (Metadata Provision Agreement):** The set of information
515 which describes the way in which data sets and metadata sets are provided by a
516 data/metadata provider. A provision agreement can be constrained in much the same
517 way as a data or metadata flow definition. Thus, a data provider can express the fact
518 that it provides a particular data flow covering a specific set of countries and topics,
519 Importantly, the actual source of registered data or metadata is attached to the
520 provision agreement (in terms of a URL). The term “agreement” is used because this
521 information can be understood as the basis of a “service-level agreement”. In SDMX,
522 however, this is informational metadata to support the technical systems, as opposed
523 to any sort of contractual information (which is outside the scope of a technical
524 specification). In version 3.0, metadata provision agreement and data provision
525 agreement are two separate artefacts.
 - 526 • **Constraint:** Data and Metadata Constraints describe a subset of a data source or
527 metadata source, and may also provide information about scheduled releases of data.
528 They are associated with data / metadata providers, provision agreements, data
529 flows, metadataflows, data structure definitions and metadata structure definitions.
 - 530 • **Structure Map:** Structure maps describes a mapping between data structure
531 definitions or dataflows for the purpose of transforming a data set into a different
532 structure. The mapping rules are defined using one or more component maps which

533 each map in turn describes how one or more components from the source data
534 structure definition map to one or more components in that of the target. Represent
535 maps act as lookup tables and specific provision is made for mapping dates and
536 times.

- 537 • **Representation Map:** Representation maps describe mappings between source
538 value(s) and target value(s) where the values are restricted to those in a code list,
539 value list or be of a certain type such as integer or string.
- 540 • **Item Scheme Map:** An item scheme map describes mapping rules between any item
541 scheme with the exception of code lists and value lists which use representation
542 maps. The version 3.0 information model provides four item scheme maps:
543 organisation scheme map, concept scheme map, category scheme map and
544 reporting taxonomy map. Organisation scheme map and reporting scheme map have
545 been omitted from the information model schematic in Figure 1.
- 546 • **Reporting Taxonomy:** A reporting taxonomy allows an organisation to link (possibly
547 in a hierarchical way) a number of cube or data flow definitions which together form a
548 complete “report” of data or metadata. This supports primary reporting which often
549 comprises multiple cubes of heterogeneous data, but may also support other
550 collection and reporting functions. It also supports the specification of publications
551 such as a yearbook, in terms of the data or metadata contained in the publication.
- 552 • **Process:** The process class provides a way to model statistical processes as a set
553 of interconnected *process steps*. Although not central to the exchange and
554 dissemination of statistical data and metadata, having a shared description of
555 processing allows for the interoperable exchange and dissemination of reference
556 metadata sets which describe processes-related concepts.
- 557 • **Hierarchy:** Describes complex code hierarchies principally for data discovery
558 purposes. The codes themselves are referenced from the code lists in which they are
559 maintained.
- 560 • **Hierarchy Association:** A hierarchy association links a hierarchy to something that
561 needs it like a dimension. Furthermore, the linking can be specified in the context of
562 another object such as a dimension in the context of a dataflow. Thus, a dimension
563 in a data structure definition could have different hierarchies depending on the
564 dataflow.
- 565 • **Transformation Scheme:** A transformation scheme is a set of Validation and
566 Transformation Language (VTL) transformations aimed at obtaining some meaningful
567 results for the user (e.g., the validation of one or more data sets). The set of
568 transformations is meant to be executed together (in the same run) and may contain
569 any number of transformations in order to produce any number of results. Thus, a
570 transformation scheme can be considered as a VTL ‘program’.

571
572

573 **3.5 SDMX Registry Services**

574 In order to provide visibility into the large amount of data and metadata which exists within
575 the SDMX model of statistical exchange, it is felt that an architecture based on a set of registry
576 services is potentially useful. A “registry” – as understood in webservices terminology – is an
577 application which maintains and stores metadata for querying, and which can be used by any
578 other application in the network with sufficient access privileges (though note that the
579 mechanism of access control is outside of the scope of the SDMX standard). It can be
580 understood as the index of a distributed database or metadata repository which is made up
581 of all the data provider’s data sets and reference metadata sets within a statistical community,
582 located across the Internet or similar network.

583
584 Note that the SDMX registry services are not concerned with the storage of data or reference
585 metadata. The assumption is that data and reference metadata lives on the sites of its data
586 and metadata providers. The SDMX registry services concern themselves with providing
587 visibility of the data and reference metadata, and information needed to access the data and
588 reference metadata. Thus, a registered data set will have its URL available in the registry,
589 but not the data itself. An application which wishes to access that data would query the
590 registry, perhaps by drilling down via a Category Scheme and Dataflow, for the URL of a
591 registered data source, and then retrieve the data directly from the data provider (using an
592 SDMX REST API query message or other mechanism).

593
594 SDMX does not require a particular technology implementation of the registry – instead, it
595 specifies the standard interfaces which may be supported by a registry. Thus, users may
596 implement an SDMX-conformant registry in any fashion they choose, provided the interfaces
597 are supported as specified in Section 5 on the Registry Specification. These interfaces are
598 expressed as XML documents, but also REST API request/response messages

599
600 The registry services discussed here can be briefly summarized:

- 601
- 602 • **Maintenance of Structural Metadata:** This registry service allows users with
603 maintenance agency access privileges to submit and modify structural metadata. In
604 this aspect the registry is acting as a structural metadata repository. However, it is
605 permissible in an SDMX structure to submit just the “stub” of the structural object,
606 such as a code list, and for this stub to reference the actual location from where the
607 metadata can be retrieved, either from a file or a structural metadata resource, such
608 as another registry.
 - 609 • **Registration of Data and Metadata Sources:** This registry service allows users with
610 maintenance agency access privileges to inform the registry of the existence and
611 location (for retrieval) of data sets and reference metadata sets. The registry stores
612 metadata about these objects, and links it to the structural metadata that give
613 sufficient structural information for an application to process it, or for an application to
614 discover its existence. Objects in the registry are organized and categorized
615 according to one or more category schemes.
 - 616 • **Querying:** The registry services have interfaces for querying the metadata contained
617 in a registry, so that applications and users can discover the existence of data sets
618 and reference metadata sets, structural metadata, the providers/agencies associated
619 with those objects, and the provider agreements which describe how the data and
620 metadata are made available, and how they are categorized.

- 621 • **Subscription/Notification:** It is possible to “subscribe” to specific objects in a
622 registry, so that a notification will be sent to all subscribers whenever the registry
623 objects are updated.

624 **3.6 RESTful Web services**

625 Web services allow computer applications to exchange data directly over the Internet,
626 essentially allowing modular or distributed computing in a more flexible fashion than ever
627 before. In order to allow web services to function, however, many standards are required:
628 for requesting and supplying data; for expressing the enveloping data which is used to
629 package exchanged data; for describing web services to one another, to allow for easy
630 integration into applications that use other web services as data resources.

631 Version 3.0 has standardized on RESTful web services with a OpenAPI specification
632 published on the SDMX Technical Working Group’s GitHub repository
633 <https://github.com/sdmx-twg>. There are five ‘resources’:

- 634 • structure – retrieval and maintenance of structural metadata
- 635 • data – retrieval of data
- 636 • schema – retrieval of XML schemas to validate specific data or metadata sets
- 637 • availability – retrieval of information on the data available for a Dataflow
- 638 • metadata – retrieval of reference metadata

639 The following conceptual example uses the ‘data’ resource to query a data repository for a
640 series identified by the key ‘M.USD.EUR.SP00.A’ in the EXR (ECB exchange rates)
641 Dataflow:

642 `https://ws-entry-point/data/dataflow/ECB/EXR/1.0.0/M.USD.EUR.SP00.A`
643

644 **4 The SDMX Information Model**

645 SDMX provides a way of modelling statistical data, and defines the set of metadata constructs
646 used for this purpose. Because SDMX specifies a number of transmission formats for
647 expressing data and structural metadata, the model is used as a mechanism for guaranteeing
648 that transformation between the different formats is lossless. In this sense, all of the formats
649 are syntax-bound expressions of the common information model.

650
651 SDMX recognizes that statistical data is structured; in SDMX this structure is termed a Data
652 Structure Definition. “Data sets” are made up of one or more lower-level “groups”, based on
653 their degrees of similarity. Each group is in turn comprised of one or more “series” of data.
654 Each series or section has a “key” - values for each of a cluster of concepts, also called
655 “dimensions” - which identifies it, and one or more “observations”, which typically combine
656 the time of the observation, and the value of the observation (e.g., measurement).
657 Additionally, metadata may be attached at any level of this structure as descriptive
658 “attributes”. Code lists (enumerations) and other patterns for representation of data and
659 metadata are also modelled.
660

661 There is some similarity between “cube” structures commonly used to process statistical data,
662 and the Data Structure Definition idea in the SDMX Information Model. It is important to note
663 that the data as structured according to the SDMX Information Model is optimized for
664 exchange, potentially with partners who may have no ability to process a “cube” of data
665 coming from complex statistical systems. SDMX time series can be understood as “slices” of
666 the cube. Such a slice is identified by its key. A "series" key consists of the values for all
667 dimensions specified by the key family except time. Thus, it is possible to reconstruct and
668 describe data cubes from SDMX-structured data, and to exchange such databases using the
669 interfaces and formats provided for that purpose in the standard. Additional objects such as
670 hierarchical code lists, constraints and structure maps make it possible to more fully model
671 the structure of cubes.

672
673 The information model also provides a view of reference metadata: a mechanism for
674 referencing the meaningful “objects” within the SDMX view of statistical exchange processes
675 (data providers, structures, provisioning agreements, dataflows, metadata flows, etc.) to
676 which metadata is attached; a mechanism for describing a set of meaningful concepts, of
677 organizing them into a presentational structure, and of indicating how their values are
678 represented. This is based on a simple, hierarchical view of reference metadata which is
679 common to many metadata systems and classification/categorization schemes. SDMX
680 provides a model (and XML and JSON formats) for both describing reference metadata
681 structures, and of reporting reference metadata according to those structures.

682
683 Version 2.0/2.1 introduced support for metadata related to the process aspects of statistical
684 exchange. A step-by-step process can be modelled; information about who is providing data
685 and reference metadata and how they are providing it can be expressed; and the technical
686 aspects of service-level agreements (and similar types of provisioning agreements) can be
687 represented.

688
689 Support for the Validation and Transformation Language (VTL) in the SDMX Information
690 Model was introduced in the July 2020 revision of 2.1 and is retained in version 3.0 with
691 minimal changes. This allows reusable VTL ‘programs’ (a cohesive set of transformation
692 statements designed to be executed together) and their associated constructs such as
693 validation rulesets and user-defined operators to be managed and exchanged as SDMX
694 structural metadata. Mappings between objects such as data sets referenced in VTL
695 programs and the actual SDMX artefacts to which they relate is essential when it comes to
696 actually executing programs, and this information can also be defined. Chapter 7 has more
697 information on VTL and its integration with SDMX.

698
699 A full UML conceptual design of the information model is set out in Section 2 of the Technical
700 Specifications.

701 **5 The SDMX Transmission Formats**

702 **5.1 SDMX-ML**

703 SDMX-ML is the XML transmission format specification for exchanging structural metadata,
704 data and reference metadata, and interacting with SDMX registry services. It is designed as
705 a general-purpose format for all automation and data / metadata exchange tasks, and
706 provides the most complete coverage.
707

708 There are four distinct types of message:

709

710

1. *Structure Definition*: For the exchange of structural metadata. A SDMX-ML structure message can carry details of any number and combination of structural metadata artefacts like DSDs, code lists and constraints.

711

712

713

714

2. *Structure-specific Data*: For the exchange of data. This format is specific to the Data Structure Definitions of the data sets (in other terms, it is DSD-specific) and is created by following mappings between the metadata constructs defined in the Structure Definition message and the technical specification of the format. It supports the exchange of large data sets in XML format, provides strict validation of conformance with the DSD using a generic XML parser, and supports the transmission of partial data sets (incremental updates) as well as whole data sets.

715

716

717

718

719

720

721

722

723

724

725

726

727

728

Many XML tools and technologies have expectations about the functions performed by an XML schema, one of which is a very direct relationship between the XML constructs described in the XML schema and the tagged data in the XML instance. Strong data typing is also considered normal, supporting full validation of the tagged data. These message types are designed to support validation and other expected XML schema functions.

729

3. *Generic Metadata*: For the exchange of reference metadata sets. ‘Generic’ means the XML elements and XML attributes are the same regardless of the metadata set.

730

731

732

4. *Registry*: All of the possible interactions with the SDMX registry services are supported using SDMX-ML interfaces and REST API calls. Submission of structural metadata content, data / metadata registrations and subscriptions is performed by a synchronous exchange of documents – a “request” message answered by a “response” message.

733

734

735

736

737

738 **5.2 SDMX-JSON**

739

SDMX-JSON is the JSON transmission format specification for exchanging structural metadata, data and reference metadata. It provides an alternative to SDMX-ML and is most suited to applications like web data dissemination.

740

741

742

743

SDMX-JSON messages serve the same function as those of the XML formats but have a different structure. For data, an important distinction is that they carry both component codes and labels which provides all the information needed to display the content in a single JSON response. The XML Structure-specific Data format by contrast carries only code IDs thus requiring applications obtain and hold structural metadata about the data set in order to display the content in human-readable form.

744

745

746

747

748

749

750

SDMX-JSON does not include messages for subscription / notification or registration registry services - SDMX-ML must be used for those purposes.

751

752

753

There are three distinct message types:

754

1. *Structure*: For the exchange structural metadata. SDMX-JSON structure messages follow the same principles as for SDMX-ML in that a single message can transmit any

755

756 number and combination of structural metadata artefacts. While the SDMX-ML and
757 SDMX-JSON messages are structured differently, it is possible to freely convert
758 between them.

759

760 2. *Data*: For the exchange of data. Unlike SDMX-ML, the structure of a SDMX-JSON
761 data message is not specific to the DSDs of the data sets so schema validation will
762 not check for compliance of the data with the DSDs.

763

764 3. *Metadata*: For the exchange of reference metadata sets.

765

766 **5.3 SDMX-CSV**

767 SDMX-CSV is the CSV transmission format specification for exchanging data and reference
768 metadata only.

769

770 SDMX-CSV provides a simple columnar format for data and metadata that can be readily
771 created and interpreted by standard software tools such as Microsoft Excel. Nevertheless, data
772 and metadata can still be converted between the CSV and the JSON / XML formats without
773 loss.

774

775 There are two distinct message types:

776 1. *Data*: For the exchange of data. Like SDMX-JSON, SDMX-CSV can include both
777 code IDs and labels which is helpful when using the data to create human readable
778 charts and dashboards.

779

780 2. *Metadata*: For the exchange of reference metadata sets.

781

782 **5.4 Formats and Messages Deprecated in Version 3.0**

783 The following formats and messages have been deprecated in version 3.0 to simplify,
784 modernise and rationalise the standard.

785

- 786 • SDMX-EDI
- 787 • SDMX-ML 1.0/2.0 Generic (time-series) data message
- 788 • SDMX-ML 1.0/2.0 Compact (time-series) data message
- 789 • SDMX-ML 1.0/2.0 Utility (time-series) data message
- 790 • SDMX-ML 1.0/2.0 Cross-Sectional data message
- 791 • SDMX-ML 2.1 Generic (Time Series) data messages (for observations, time-series and
792 cross-sectional data)
- 793 • SDMX-ML 2.1 Structure Specific Time Series data message

794 The following messages were deprecated in version 3.0 as a consequence of the deprecation
795 of the SOAP web services:

796 • SDMX-ML Query messages

797 • SDMX-ML Submit Structure Request messages

798

799 **6 Dependencies on SDMX content-oriented guidelines**

800 The technical standards proposed here are designed so that they can be used in conjunction
801 with other SDMX guidelines which are more closely tied to the content and semantics of
802 statistical data exchange. The SDMX Information Model works equally well with any statistical
803 concept, but to encourage interoperability, it is also necessary to standardize and harmonize
804 the use of specific concepts and terminology. To achieve this goal, SDMX creates and
805 maintains guidelines for cross-domain concepts, terminology, and structural definitions.
806 There are three major parts to this effort.

807 **6.1 Cross-Domain Concepts**

808 The SDMX Cross-Domain Concepts is a content guideline concerning concepts which are
809 used across statistical domains. This list is expected to grow and to be subject to revision as
810 SDMX is used in a growing number of domains. The use of the SDMX Cross-Domain
811 Concepts, where appropriate, provides a framework to further promote interoperability
812 among organisations using the technical standards presented here. The harmonization of
813 statistical concepts includes not only the definitions of the concepts, and their names, but
814 also, where appropriate, their representation with standard code lists, and the role they play
815 within data structure definitions and metadata structure definitions.

816
817 The intent of this guideline is two-fold: to provide a core set of concepts which can be used
818 to structure statistical data and metadata, to promote interoperability between systems
819 (“structural metadata”, as described above); and to promote the exchange of metadata more
820 widely, with a set of harmonized concept names and definitions for other types of metadata
821 (“reference metadata”, as defined above.)

822

823 **6.2 Metadata Common Vocabulary**

824 The Metadata Common Vocabulary is an SDMX guideline which provides definition of terms
825 to be used for the comparison and mapping of terminology found in data structure definitions
826 and in other aspects of statistical metadata management. Essentially, it provides ISO-
827 compliant definitions for a wide range of statistical terms, which may be used directly, or
828 against which other terminology systems may be mapped. This set of terms is inclusive of
829 the terminology used within the SDMX Technical Standards.

830

831 The MCV provides definitions for terms on which the SDMX Cross-Domain Metadata
832 Concepts work is built.

833 **6.3 Statistical Subject-Matter Domains**

834 The Statistical Subject-Matter Domains is a listing of the breadth of statistical information for
835 the purposes of organizing widespread statistical exchange and categorization. It acts as a
836 standard scheme against which the categorization schemes of various counterparties can be
837 mapped, to facilitate interoperable data and metadata exchange. It serves another useful
838 purpose, however, which is to allow an organization of corresponding “domain groups”, each
839 of which could define standard data structure definitions, concepts, etc. within their domains.
840 Such groups already exist within the international community. SDMX would use the Statistical
841 Subject-Matter Domains list to facilitate the efforts of these groups to develop the kinds of
842 content standards which could support the interoperation of SDMX-conformant technical
843 systems within and across statistical domains. The organisation of the content of such
844 schemes is supported in SDMX as a Category Scheme.

845
846 SDMX Statistical Subject-Matter Domains will be listed and maintained by the SDMX Initiative
847 and will be subject to adjustment.

848 **6.4 SDMX Concept Roles**

849 These guidelines define the standard set of SDMX Concept Roles and their use. This set of
850 standard SDMX Concepts are implemented as a cross-domain Concept Scheme that defines
851 the set of concept roles and gives examples on concept role implementation in SDMX 2.0,
852 2.1 and 3.0. A concept role gives a particular context to a concept for easy and systematic
853 interpretation by machine processing and visualization tools. For example, the concepts
854 REPORTING_AREA and COUNTERPART_AREA are different concepts but they are both
855 geographical characteristics, therefore they can be associated with the same concept role
856 ID: "GEO". This allows visualization systems to interpret these concepts as geographical data
857 in order to generate maps. The implementation of concept roles is different in versions 2.0
858 and 2.1/3.0 of the SDMX technical standard. Specifically for SDMX 3.0, this set of roles is
859 considered a normative list that must be interpreted in the same way by all organisations.
860 Additional roles may be provided via the standard roles' mechanism in SDMX 3.0, i.e., via
861 Concept Schemes; the semantics of these roles have to be agreed bilaterally in data
862 exchanges. The Concept Roles are available as an SDMX Concept Scheme on the SDMX
863 Global Registry.

864 **7 Validation and Transformation Language**

865 For many years the SDMX initiative has been fostering and supporting the development of a
866 standard calculation language, called Validation and Transformation Language (VTL). A
867 blueprint for defining calculations was already described in the original SDMX 2.1
868 specifications (package 13 of the Information Model - "Transformations and Expressions"). It
869 was just a basic framework that required further developments to become operational in order
870 to achieve a calculation language able to manipulate SDMX artefacts.

871
872 These developments started in late 2012 and were put in charge of the Validation and
873 Transformation Language Task Force (VTL TF), which included members of the SDMX
874 Technical Working Group (TWG) and Statistical Working Group (SWG), besides experts
875 coming from the DDI and GSIM communities. The intent was to define a standard language
876 to be implemented in SDMX and applicable also to GSIM and DDI. This brought to the
877 publication of the VTL 1.0 in 2015. Then new requirements came from a number of proofs of
878 concepts and tests of VTL 1.0 made by several organisations and triggered a large
879 improvement of the language. A new provisional version, the VTL 1.1, was released in public
880 consultation in 2017. The high number of comments received triggered another phase of
881 intensive work, with the main goal of achieving a more robust and forward compatible version.
882 Finally, the VTL 2.0 was published between April and July 2018 (see the SDMX website).

883
884 The implementation of the VTL 2.0 in SDMX started in late 2018 and was published as an
885 incremental revision to the SDMX 2.1 standards in July 2020. It allows users to write VTL
886 2.0 programs for validating and transforming SDMX data, to store these programs in a SDMX
887 metadata registry and to exchange them through SDMX messages, also together the
888 definition of the data structures of the involved data.

889

890 The Transformations and Expressions package for modelling VTL programs in the SDMX
891 information model is explained in Section 2 of the Technical Specifications with further
892 detailed usage and implementation guidance given in Section 6.
