1. INTRODUCTION

This Data Report Addendum is a supplement to the Remedial Investigation Data Report (Tetra Tech 2007) and is a component of the Remedial Investigation/Feasibility Study (RI/FS) Work Plan (Tetra Tech 2008a) for the Lockheed West (LW) Seattle Superfund Site (Site) (Figure 1-1). This Data Report Addendum is submitted on behalf of Lockheed Martin Corporation (LMC) and presents data resulting from the sampling and analysis activities described in the Clam Reconnaissance Survey Tissue and Sediment Quality Assurance Project Plan (QAPP) (Tetra Tech 2008b).

1.1 BACKGROUND

The reconnaissance survey was designed to provide data to evaluate the presence/absence and relative abundance of populations of deposit-feeding clams (i.e., *Macoma* sp.) at the LW site. The data obtained from the reconnaissance survey was be used to determine if sufficient clam populations were present at the site to conduct representative tissue collection and chemical analysis. An adequate abundance of clams was identified by the reconnaissance survey of LW, which resulted in a sampling and analysis program used for collecting clam tissue data. Specific objectives included the following:

- Characterize the clam population at the LW site, and determine if there is a sufficient population of deposit-feeding clams;
- Collect site-specific clam tissue and collocated sediment samples from the one intertidal and five sub-tidal areas for subsequent chemical analysis;
- Derive a site-specific shellfish biota-sediment accumulation factor (BSAF) from the analytical results generated from the clam tissue and collocated sediment samples; and
- Compare the site-specific BASF results with the literature-derived BASF values.

These site-specific BSAFs will be compared to literature-derived BSAFs, as modified from the Lower Duwamish Waterway (LDW) QAPP for sediment and tissue collection, to verify that the values were sufficiently conservative for use in modeling tissue concentrations for the ecological and human health risk assessments. It is understood that a decision on whether to use the site-specific or the literature-derived BSAF values is a future management decision for the U.S. Environmental Protection Agency (EPA). This rationale is based on the understanding that deposit-feeder clams will more closely reflect sediment contaminant levels

than filter-feeder clams or other benthic organisms that may contain a significant part of their body burdens from non-sediment sources.

1.2 PURPOSE AND ORGANIZATION OF THIS DOCUMENT

The purpose of this Data Report Addendum is to supplement the Data Report and document the field data collection activities and results from additional sampling, including clam tissue and co-located sediment samples, and analysis activities. Intertidal clam tissue and co-located sediment sampling was conducted on April 8, 2008, during low tide. Subtidal clam reconnaissance survey was performed April 9–11, 2008. Subtidal clam collection and co-located sediment sampling was conducted on May 13–14, 2008. This report presents the chemical analysis results of the clam tissue and co-located sediment samples.

This Data Report Addendum summarizes the results of field sampling activities and identifies any deviations from the QAPP. This report consists of a sample identification matrix that relates sample identification numbers to sample locations, a map of sample locations, and tables of chemical analysis data. These data were validated by a third-party validator in accordance with the Clam Reconnaissance Survey and Tissue QAPP (Tetra Tech 2008b). Field notes, log sheets, photos, laboratory data reports, and data validation reports are included as appendices. This report does not interpret these data. Instead, the data will be evaluated as part of the RI/FS report.

This Data Report Addendum is organized into the following sections:

- Section 2 – Methods used to conduct the field investigations and laboratory methods of analysis.
- Section 3 – Discussion of the data quality and summary of sample results.
- Section 4 – References.
- Figures and tables are provided at the end of the Data Report Addendum text.
- Appendix A includes the photos documenting the intertidal and subtidal tissue and sediment sample collection.
- Appendix B includes all field notes, log sheets, and chain-of-custody forms documenting the intertidal and subtidal tissue and sediment sampling.
- Appendix C includes data validation reports for the results reported herein.
- Appendix D includes the chemistry laboratory data reports for the results reported herein.

- Appendix E includes the updated project database including historical and 2007 sample results, and the 2008 clam tissue and sediment sampling data.

2. FIELD ACTIVITIES AND METHODS

Field activities included the intertidal clam reconnaissance survey and tissue and sediment sampling performed April 8, 2008, the sub-tidal clam reconnaissance survey performed April 9–11, 2008, and the subtidal tissue and sediment sampling performed May 13–14, 2008, at the LW project site. EPA authorized the implementation of the RI field work described in the Work Plan. The field work was conducted in two phases: Phase 1, the clam reconnaissance survey of the intertidal and sub-tidal areas of the LW site, which was to determine the presence or absence and relative abundance of clam populations (i.e., deposit feeding clams) at the LW site, and Phase 2, clam tissue and sediment sampling and analysis. Phases 1 and 2 of the intertidal clam reconnaissance survey and tissue and sediment sampling were performed simultaneously.

2.1 CLAM RECONNAISSANCE SURVEY AND TISSUE AND SEDIMENT SAMPLING PROCEDURES

The clam reconnaissance survey and tissue and sediment sampling and analysis efforts were performed according to the QAPP (Tetra Tech 2008b), and a synopsis of these activities is provided below. The LW site was divided into six areas for the reconnaissance survey (Figure 2-1) based on the summary of existing information, knowledge of historical site uses, current site-use plans, and recent high-resolution site bathymetry. Area 1 represents the intertidal habitat, and Areas 2 through 6 represent the sub-tidal habitat of the LW site.

The intertidal area clam reconnaissance survey and tissue and sediment sampling were performed simultaneously on April 8, 2008. The actual sample locations within the intertidal study area were determined in the field by using clam shows or digging success to guide the sampling. The Phase 1 component of the intertidal survey consisted of surveying for all deposit-feeder type clams (i.e., *Macoma* sp.) over one low tide cycle.

The intertidal clam reconnaissance survey methods were generally based on the Washington Department of Fish and Wildlife guidance (Campbell 1996). At each sampling point, approximately 0.028 cubic meters (m^3) (1.0 cubic foot [ft^3]) of substrate were removed and sorted. All clams present within the substrate were removed, identified, measured, and non-deposit-feeder clams were replaced with the removed substrate in the original hole. All deposit-feeding clams were retained. All observations of other invertebrate species identified during the intertidal survey are recorded in Tables 2-1 and 2-2.

Per the QAPP, at each Phase 1 sub-tidal clam reconnaissance survey area, three clam reconnaissance sampling locations were evaluated for adequate clam abundance for each of the five sub-tidal areas. From each clam reconnaissance sample location, three sediment grabs were collected, sediment sieved, and all observed clams were identified, counted, and weighed. The field results and summary tables are shown in Tables 2-3 and 2-4.

Based on the results of the Reconnaissance surveys, tissue and co-located sediment sampling and analysis were conducted in the intertidal and sub-tidal Areas 3, 4, and 5 of the LW site. The sample locations selected contained adequate numbers of deposit-feeding clam populations as specified in the QAPP for clam tissue and co-located sampling. Tissue and co-located sediment sampling was not conducted at Areas 2 and 6 due to an inadequate number of deposit-feeding clams present during the reconnaissance survey. The basis for evaluating whether to proceed with tissue analyses is defined in the QAPP.

The clam reconnaissance and tissue and co-located sediment sampling and analysis were performed in accordance with the QAPP. Clam tissue and sediment samples were submitted to Columbia Analytical Services, Inc. (CAS) for analysis.

2.1.1 Horizontal Control

Intertidal clam tissue and co-located sediment sampling locations were collected using a hand-held Trimble® GEO-XT GPS unit. Actual locations where samples were collected were recorded at the time of collection using Integrated WAAS correction in the field. Horizontal positioning was recorded in State Plane Washington North, North American Datum (NAD) 1983 coordinate system.

Subtidal sampling locations were collected using a Trimble Ag 132 DGPS and a computer running HYPACK® hydrographic survey software. Actual locations where samples were collected were recorded at the time of collection. Horizontal positioning was recorded in State Plane Washington North, NAD 1983 coordinate system to the nearest 0.1 foot.

2.1.2 Intertidal Sample Collection

Intertidal tissue and co-located sediment sampling were conducted concurrently with the intertidal clam reconnaissance survey on April 8, 2008. All *Macoma* sp. clams found in the intertidal area were collected, weighed, and depurated for tissue sample A1-IT. A 1-foot-long by 2-inch diameter surface sediment core was collected from each location where *Macoma* sp. clams were present and composited to form sediment sample A1-IT. The tissue and co-located sediment samples are composite samples of the intertidal area. The sample locations

are identified on Figure 2-2. The sample locations are included in Table 2-5. Copies of the field logs are included in Appendix B of this report.

2.1.3 Subtidal Sample Collection

Three subtidal areas (3a, 4b, and 5a) were sampled for tissue and co-located sediment samples at the LW Site on May 13–14, 2008, as shown in Figure 2-1 and Table 2-5. The sediment samples were representative of the upper 20 centimeters of sediment. All tissue and sediment sampling were conducted as described in the QAPP (Tetra Tech 2008b). A minimum of 10 sediment grabs (2 square meters [m^2] of sediment) were collected at each location to achieve the minimum tissue mass goal for the *Macoma* sp. clams. At location 3a, 16 sediment grabs were collected in efforts to locate more clams for a greater tissue mass.

Equipment decontamination procedures and sample handling procedures detailed in the QAPP (Tetra Tech 2008b) were followed closely to prevent cross-contamination of the samples. Quality Assurance (QA)/Quality Control (QC) samples were collected to evaluate the effectiveness of these QC measures.

Subtidal sampling was conducted from a vessel using a modified, single 0.2 m^2 Power grab sampler deployed from an A-frame provided and operated by Research Support Services, Inc. The sampler was lowered to the bottom, retrieved and placed in a stable position on the boat deck. The top covers were opened and the sample was checked for acceptability using Puget Sound Estuary Program (PSEP) criteria (e.g., relatively clear overlying water present and no significant winnowing or other disturbance). The overlying water was siphoned off the top of the sampler, and then surface sediment was collected by hand pushing three, 1-foot-long by 2-inch diameter poly-liner cores from the center of the undisturbed sampler. The cores were held in a temporary stainless steel bowl until it was determined if *Macoma* sp. clams were present; if so, the sediment was thoroughly homogenized in a separate stainless steel bowl with the sediment from the location's other acceptable grabs. The sediment was portioned into sampling jars provided by the laboratory. These samples were placed into coolers and covered with ice to maintain the temperature at 4 degrees Celsius ($^{\circ}C$) during transport to CAS in Kelso, Washington, for chemical analysis.

Clams collected from each sample location were weighed, counted, and allowed to depurate for 24 hours in site water in separate sample buckets. After depuration, clams were placed in glass sampling jars provided by the laboratory. The samples were placed into coolers and covered with ice to maintain the temperature at $4^{\circ}C$ during transport to the laboratory.

Field sampling logs and chain of custody forms are included in Appendix B. Results of the chemical analyses are presented in Section 3 of this report.

2.1.4 Quality Assurance/ Quality Sampling Activities

The objective of the QA/QC sampling was to ensure that acceptable sampling practices were followed during field activities. Laboratory QC analyzes were performed on the abundant tissue from tissue sample A1-IT (see Section 2.1.5, Sample Identification). One sediment duplicate sample (3D-S) was collected to determine the variability in chemical concentrations between samples of the same sediment. One equipment rinsate blank (RB-S) was taken to document the effectiveness of decontamination procedures.

The chemistry results, analysis methods, reporting limits, and detection limits for the laboratory QC samples are included in Appendix D; the rinsate blank sample results are provided in Table 3-2.

QA/QC samples were handled and transported in the same manner as the regular samples.

2.1.5 Sample Identification

Samples are listed in Tables 2-2, 2-3, 3-1, and 3-2. The samples were coded by sample type. Intertidal samples were identified as Area 1-Intertidal (A1-IT) and designated tissue or sediment on the chain of custody. Subtidal samples were labeled by their area and location of collection (3A, 4A, or 5A), then designated as tissue (C) or sediment (S) sample (i.e., 3A-C). The rinsate blank was identified as RB-1.

2.1.6 Deviations from the QAPP

There were no deviations from the QAPP (Tetra Tech 2008b).

2.2 LABORATORY ANALYSIS

This section includes an overview of laboratory methods used for analysis of intertidal and subtidal tissue and sediment samples.

2.2.1 Tissue Chemistry Methods

Tissue samples were analyzed for COPCs by the methods listed in Table 2-6. The required detection limits were intended to be consistent with risk-based-low-level detection limits of the Lower Duwamish project.

2.2.2 Sediment Chemistry Methods

Co-located sediment samples were analyzed for COPCs by the methods listed in Table 2-7. The required detection limits were intended to be consistent with risk-based-low-level detection limits of the Lower Duwamish project.

2.2.3 Deviations from Approved Plans

Methods followed the approved plans except the following:

- The laboratory reported additional parameters: Total Hepta-Dioxins/Furans, Total Hexa-Dioxins/Furans, Total Penta-Dioxins/Furans, Total Tetra-Dioxins/Furans, Tetrabutyltin, Endrin aldehyde, and Hexachlorobutadiene.

3. SAMPLE RESULTS

This section discusses the results of the chemical analyses for tissue and co-located sediment samples collected at the Site during the April and May 2008 sampling events. Results for all these analyses are summarized below.

3.1 DATA QUALITY EVALUATION

Two data packages, corresponding to individual sample delivery groups, were generated by CAS. The CAS facility located in Kelso, Washington, performed the requested analyses, with the exception of dioxin-furan analyses, which were analyzed by the CAS facility located in Houston, Texas. The data packages were validated by Laboratory Data Consultants, Inc. (LDC), an independent validation firm. The validation is summarized by LDC in two data validation reports. Based on review of sediment and tissue data, the overall data quality objectives specified in the QAPP were met (Tetra Tech 2008b). The data validation reports are provided in Appendix C and are summarized below.

3.1.1 Validation Levels and Criteria

Level 3 data validation was performed on the two data packages. Level 3 data validation consists of an evaluation of the following items, as summarized in the data packages: holding time, calibration, blank, surrogate spike, matrix spike/matrix spike duplicate, laboratory control sample, and some method-specific requirements. Data validation was performed using the guidance as described in EPA's *National Functional Guidelines for Inorganic Data Review* (EPA 2004), *National Functional Guidelines for Organic Data Review* (EPA 1999), and *National Functional Guidelines for Polychlorinated Dioxins/Dibenzofurans Data Review* (EPA 2005). Data were validated in accordance with criteria specified in the EPA validation guidance and the analytical methods. Validated data are qualified in cases when the criteria were not met or as deemed appropriate, based on the professional judgment of the validator.

3.1.2 Qualified Data

The majority of analytical data are within control limits; however, there were several cases when control limits are not met. Data qualifiers were applied when control limits were not met.

Qualified data are summarized in Appendix D. Qualifiers were assigned due to the following issues: calibration outliers, blank contaminants, laboratory control sample or matrix spike recovery outliers, matrix duplicate outliers, and differences between results obtained on two gas chromatograph columns. Some of the reported results represent approximate

concentrations due to these issues and are qualified as estimated (J/UJ). Some results are qualified as not detected (U) due to the likelihood of trace contamination, as demonstrated in analytical blanks. No data were rejected.

Control limit exceedances such as those encountered for this project are typical. The number and severity of exceedances for this project are considered to be within the expected range, and associated data have been appropriately qualified as indicated above. Overall, project objectives were met and the laboratory analyses are considered usable for the intended purpose.

3.1.3 Field Duplicate Samples

One field duplicate set, consisting of sediment samples 3A-S and 3D-S, was collected and analyzed. With the exception of dioxins/furans, the field duplicate set exhibited very good agreement, with relative percent difference values for detected analytes ranging from 0 to 34 percent. For dioxin/furans, the concentrations of detected analytes for Sample 3A-D were approximately three times greater than the concentrations for Sample 3A-S. The reason for the discrepancy is unknown.

3.2 TISSUE CHEMISTRY RESULTS

Three tissue samples (A1-IT, 4B-C, and 5A-C) were analyzed for the full list of COPCs described in the QAPP 2008, such as lipids, PCB Aroclors (PCBs), individual PAHs, dioxins, furans, TBT, metals, and pesticides. Tissue sample 3A-C contained insufficient tissue mass for the full list of COPCs to be analyzed, which, as a result, 3A-C was analyzed for lipids, PCBs, and metals only. The tissue sample analysis results and methods, reporting limits, and detection limits are detailed in Table 3-1. The list of COPCs was determined based on ranking of preliminary screening risk estimates for human health and ecological receptors, and based on the risk drivers identified for the LDW site for both human health and ecological receptors. Lipid data are essential for BSAF development for PCBs, so lipids are also listed as a higher priority over other COPC analyte groups. The limited COPC analysis for tissue sample 3A-C was based on this priority ranking of COPCs.

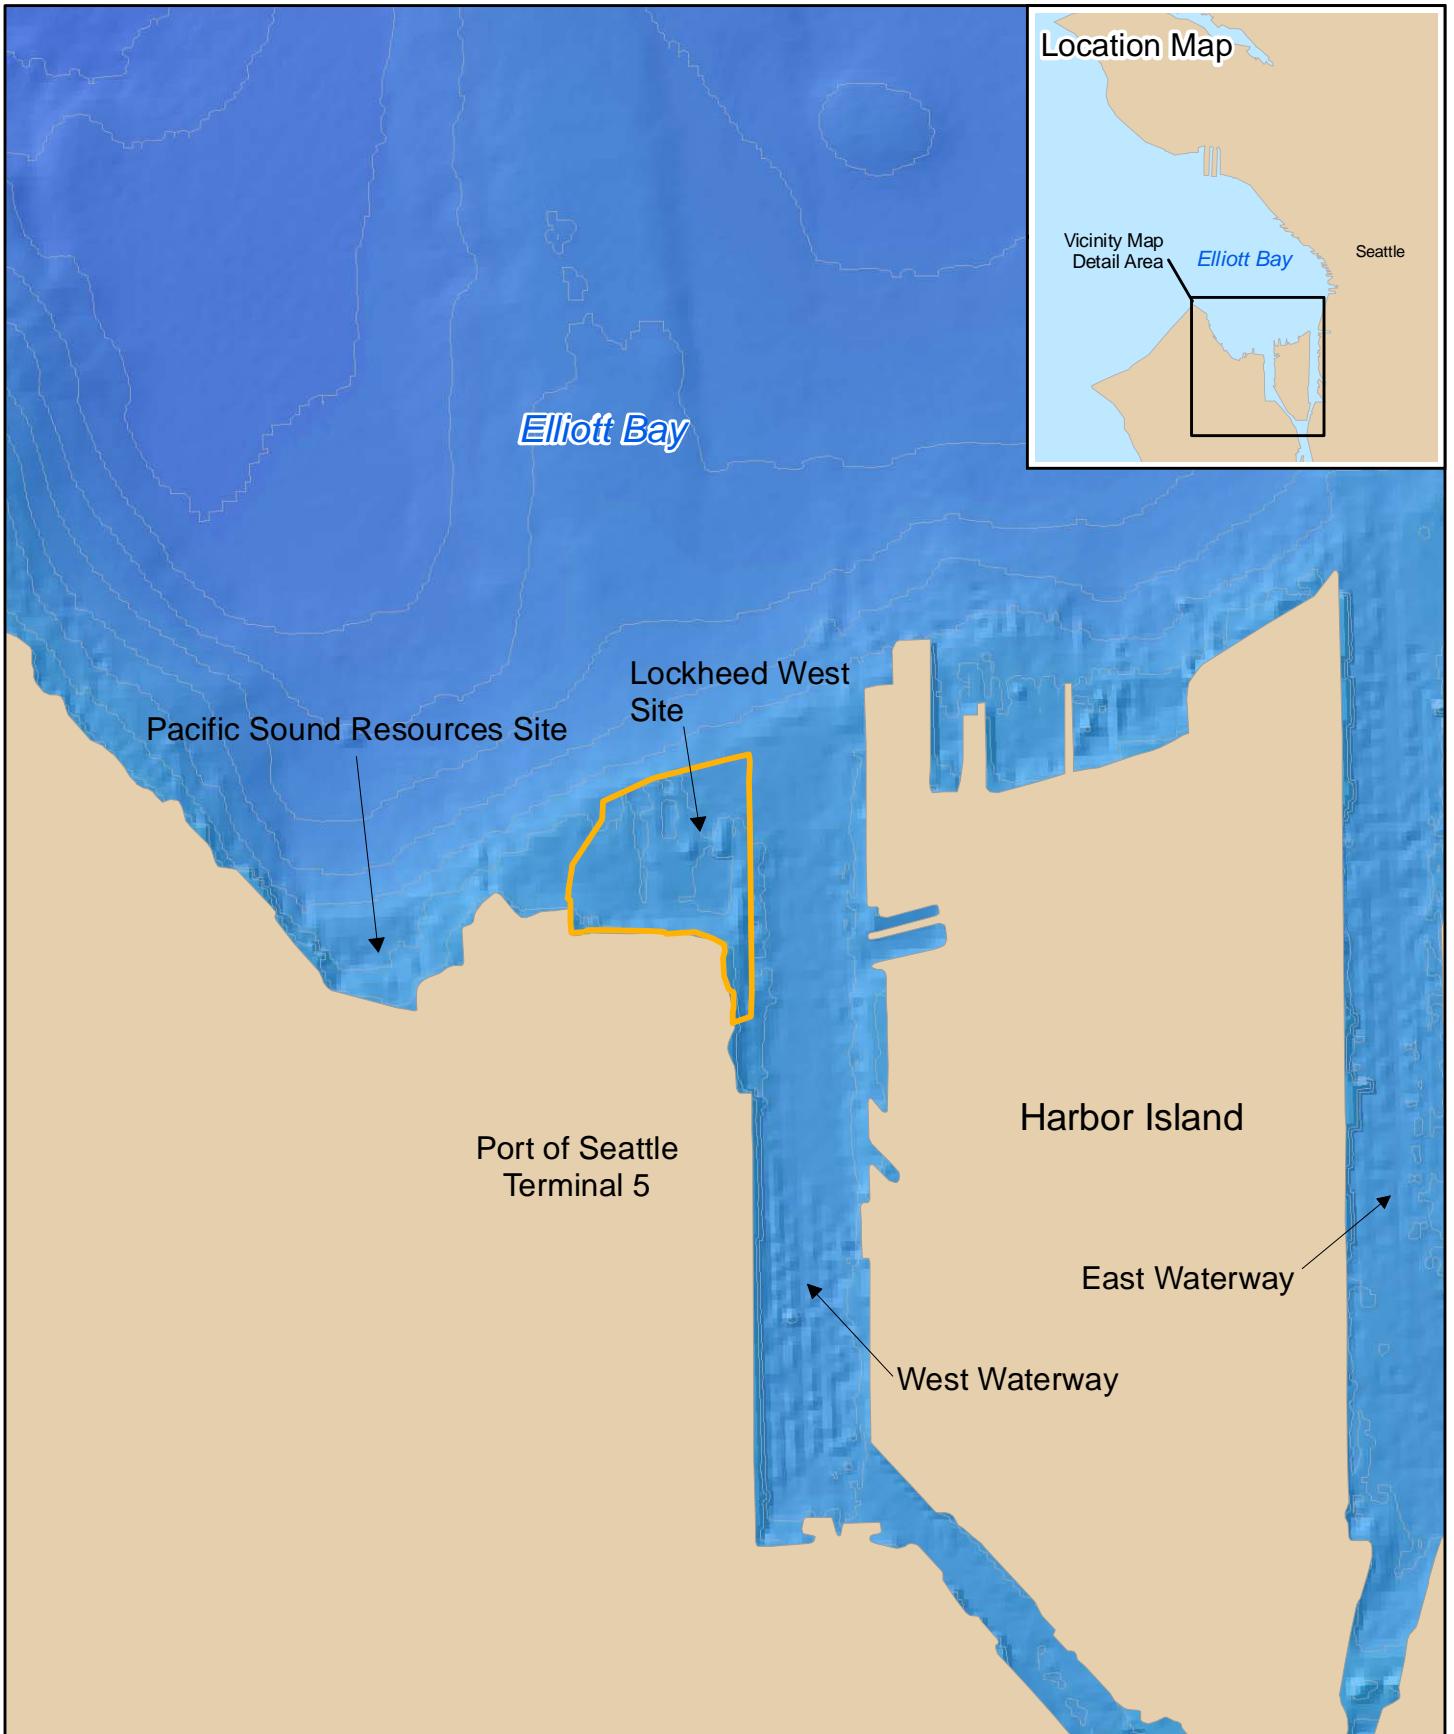

3.3 SEDIMENT CHEMISTRY RESULTS

The co-located sediment samples included surface (0 to upper 20 centimeters] grab samples. The sediment samples were analyzed for the COPCs listed in the QAPP, which reflect the tissue sample COPCs. Although tissue sample 3A-C was analyzed for a limited COPC list, the co-located sediment sample was analyzed for all listed COPCs. The sediment analysis results and methods, reporting limits, and detection limits are provide in Table 3-2.

Notes:

a) RLs and MDLs from Columbia Analytical Services Laboratory.

b) Dioxin-like PCB and dioxin/furan congeners will be evaluated as toxic equivalents (TEQs) in the risk assessments, rather than as individual congeners. However, because TEQs are calculated, rather than measured by the laboratory, RBCs for individual con-

c) Total chlordane is the sum of oxychlordane, alpha- and gamma-chlordane, and cis- and trans-nonachlor. RL and MDL are the highest RL and MDL for the chlordane-related compounds. Lab reports as individual analytes.

d) Dioxin/furan MRL's are based on EN 1948 calibration standards. MDL's are based on 30 gram samples size.

Note: Samples with high moisture contents or matrix interference may have detection limits higher than those listed.

Notes:

a) RLs and MDLs from Columbia Analytical Services Laboratory.

b) Dioxin-like PCB and dioxin/furan congeners will be evaluated as toxic equivalents (TEQs) in the risk assessments, rather than as individual congeners. However, because TEQs are calculated, rather than measured by the laboratory, RBCs for individual congener

c) Total chlordane is the sum of oxychlordane, alpha- and gamma-chlordane, and cis- and trans-nonachlor. RL and MDL are the highest RL and MDL for the chlordane-related compounds. Lab reports as individual analytes.

d) Dioxin/furan MRL's are based on EN 1948 calibration standards. MDL's are based on 30 gram samples size.

Note: Samples with high moisture contents or matrix interference may have detection limits higher than those listed.

Sample Date			4/8/2008			5/14/2008			5/13/2008			5/13/2008		
Parameter	Method	Units	Result	Lab Q	Val Q	Result	Lab Q	Val Q	Result	Lab Q	Val Q	Result	Lab Q	Val Q

b) Dioxin-like PCB and dioxin/furan congeners will be evaluated as toxic equivalents (TEQs) in the risk assessments, rather than as individual congeners. However, because TEQs are calculated, rather than measured by the laboratory, RBCs for individual congeners are presented to facilitate comparison with RLs for those congeners. In reality, risks will be assessed based on sums of these congeners (normalized per their relative toxicity to TCDD), and thus comparison to RLs on a congener-specific basis is somewhat uncertain.

c) Total Chlordane calculated by TtEC. Total chlordane is the sum of oxychlordane, alpha- and gamma-chlordane, and cis- and trans-nonachlor. RL and MDL are the highest RL and MDL for the chlordane-related compounds. Lab reports as individual analytes.

d) Dixon/furans MRL's are based on En a948 calibration standards. MDL's are based on 10 gram sample size.

Notes:

IT - Intertidal tissue sample

mg/kg= milligrams per kilogram

µg/kg= microgram per kilogram

ww= wet weight

dw= dry weight

n/a= not available

Laboratory Qualifiers (Lab Q):
For Metals:

N- The Matrix Spike sample recovery is not within control limits. See case narrative.

For Organics:

B - The analyte was found in the associated method blank at a level that is significant relative to the sample result.

D - Result reported from a dilution.

J - Result is an estimated concentration that is less than the MRL but greater than or equal to the MDL.

N - The result is presumptive. The analyte was tentatively identified, but a confirmation analysis was not performed.

P - The GC or HPLC confirmation criteria was exceeded. The relative percent difference is greater than 40% between the two analytical results.

U - Result was not detected at or above the MRL/MDL.

i - The MRL/MDL has been elevated due to a chromatographic interference.

For Dioxins/Furans:

B- Indicates the associated analyte is found in the method blank, as well as in the sample.

J- Indicated an estimated value that is less than the MRL but greater than or equal to the EDL.

K- Indicates an estimated maximum possible concentration for the associated compounds.

U- Indicates the compound was analyzed and not detected.

Data Validation Qualifiers (Val Q):

U - Result should be considered not detected at the quantitation limit shown.

J - Result is an estimated concentration.

UJ - The compound was not detected and the sample detection limit should be considered an estimated value.

Footnotes:

- a) RLs and MDLs from Columbia Analytical Services Laboratory.
- b) Dioxin-like PCB and dioxin/furan congeners will be evaluated as toxic equivalents (TEQs) in the risk assessments, rather than as individual congeners. However, because TEQs are calculated, rather than measured by the laboratory, RBCs for individual congeners are presented to facilitate comparison with RLs for those congeners. In reality, risks will be assessed based on sums of these congeners (normalized per their relative toxicity to TCDD), and thus comparison to RLs on a congener-specific basis is somewhat uncertain.
- c) Total Chlordane calculated by TiEC. Total chlordane is the sum of oxychlordane, alpha- and gamma-chlordane, and cis- and trans-nonachlor. RL and MDL are the highest RL and MDL for the chlordane-related compounds. Lab reports as individual analytes.
- d) Dixon/furans MRL's are based on EN 1948 calibration standards. MDL's are based on a 30 gram sample size.

Notes:

IT - Intertidal sediment sample
 mg/kg= milligrams per kilogram
 µg/kg= microgram per kilogram
 ww= wet weight
 dw= dry weight

Laboratory Qualifiers (Lab Q):

For Metals:

B - Result is an estimated concentration that is less than the MRL but greater than or equal to the MDL.

N- The Matrix Spike sample recovery is not within control limits. See case narrative.

U- The compound was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL.

*- The duplicate was not within control limits. See case narrative.

For Organics:

B - The analyte was found in the associated method blank at a level that is significant relative to the sample result.

D - Result reported from a dilution.

J - Result is an estimated concentration that is less than the MRL but greater than or equal to the MDL.

N - The result is presumptive. The analyte was tentatively identified, but a confirmation analysis was not performed.

P - The GC or HPLC confirmation criteria was exceeded. The relative percent difference is greater than 40% between the two analytical results.

U - Result was not detected at or above the MRL/MDL.

i - The MRL/MDL has been elevated due to a chromatographic interference.

For Dioxins/Furans:

B- Indicates the associated analyte is found in the method blank, as well as in the sample.

E- Indicates an estimated value-used when the analyte concentration exceeds the upper end of the linear calibration range.

J- Indicated an estimated value that is less than the MRL but greater than or equal to the EDL.

K- Indicates an estimated maximum possible concentration for the associated compounds.

U- Indicates the compound was analyzed and not detected.

Data Validation Qualifiers (Val Q):

U - Result should be considered not detected at the quantitation limit shown.

J - Result is an estimated concentration.

UJ - The compound was not detected and the sample detection limit should be considered an estimated value.
