36 Abstract

37 SARS-Cov-2 (severe acute respiratory disease coronavirus 2), which causes Coronavirus Disease 2019
38 (COVID19) was first detected in China in late 2019 and has since then caused a global pandemic. While
39 molecular assays to directly detect the viral genetic material are available for the diagnosis of acute
40 infection, we currently lack serological assays suitable to specifically detect SARS-CoV-2 antibodies. Here
41 we describe serological enzyme-linked immunosorbent assays (ELISA) that we developed using

42 recombinant antigens derived from the spike protein of SARS-CoV-2. Using negative control samples
43 representing pre-COVID 19 background immunity in the general adult population as well as samples
44 from COVID19 patients, we demonstrate that these assays are sensitive and specific, allowing for
45 screening and identification of COVID19 seroconverters using human plasma/serum as early as two days
46 post COVID19 symptoms onset. Importantly, these assays do not require handling of infectious virus,
47 can be adjusted to detect different antibody types and are amendable to scaling. Such serological assays
48 are of critical importance to determine seroprevalence in a given population, define previous exposure
49 and identify highly reactive human donors for the generation of convalescent serum as therapeutic.
50 Sensitive and specific identification of coronavirus SARS-Cov-2 antibody titers may, in the future, also
51 support screening of health care workers to identify those who are already immune and can be
52 deployed to care for infected patients minimizing the risk of viral spread to colleagues and other
53 patients.

54

55 Introduction

56 On December 31st, 2019 China reported first cases of atypical pneumonia in Wuhan, the capital of Hubei
57 province. The causative virus was found to be a betacoronavirus, closely related to the severe acute
58 respiratory syndrome coronavirus (SARS-CoV-1) from 2003 and similar to *Sarbecoviruses* isolated from
59 bats.^{1,2} It was therefore termed SARS-CoV-2 and the disease it causes was named COVID19 (COronaVirus
60 Disease 2019).³ The outbreak in Wuhan expanded quickly and led to the lockdown of Wuhan, the Hubei
61 province and other parts of China. While the lockdown, at least temporarily, brought the situation under
62 control in China, SARS-CoV-2 spread globally causing a pandemic with, so far, 1,700,000 infections and
63 107,000 fatalities (as of April 11th, 2020).

64 Nucleic acid tests that detect the SARS-CoV-2 RNA genome were quickly developed and are now widely
65 employed to diagnose COVID19 disease.^{4,5} However, there remains a great need for laboratory assays
66 that measure antibody responses and determine seroconversion. While such serological assays are not
67 well suited to detect acute infections, they support a number of highly relevant applications. First,
68 serological assays allow us to study the immune response(s) to SARS-CoV-2 in a qualitative and
69 quantitative manner. Second, serosurveys are needed to determine the precise rate of infection in an
70 affected area, which is an essential variable to accurately determine the infection fatality rate. Third,
71 serological assays will allow for the identification of individuals who mounted strong antibody responses
72 and who could serve as donors for the generation of convalescent serum therapeutics. Lastly, serological
73 assays will potentially permit to determine who is immune and who is not. This information may be very
74 useful for deploying immune healthcare workers in a strategic manner as to limit the risk of exposure
75 and inadvertent spread of the virus. It could also allow a certain proportion of the population that has
76 already acquired immunity to go back to 'normal life'. Of course, parallel studies that determine which
77 antibody titers correlate with protection are needed to support these potential measures.

78 *Sarbecoviruses* express a large (approximately 140 kDa) glycoprotein termed spike protein (S, a
79 homotrimer), which mediates binding to host cells via interactions with the human receptor angiotensin
80 converting enzyme 2 (ACE2).⁶⁻⁸ The S protein is very immunogenic with the receptor-binding domain
81 (RBD) being the target of many neutralizing antibodies.⁹ Individuals infected with coronaviruses typically
82 mount neutralizing antibodies, which might be associated with some level of protection for a period of
83 months to years¹⁰⁻¹², and a neutralizing response has been demonstrated for SARS-CoV-2 in an individual

84 case from day 9 onwards.¹³ Serum neutralization can be measured using replication competent virus but
85 the process requires several days and must be conducted in biosafety level 3 laboratory containment for
86 SARS-CoV-2. Potentially, pseudotyped viral particle based entry assays using lentiviruses or vesicular
87 stomatitis virus could be used but these reagents are not trivial to produce. A simple solution is the use
88 of a binding assay, e.g. an enzyme linked immunosorbent assays (ELISA), with recombinant antigen as
89 substrate. Here we report the development of such an assay and provide a protocol for both
90 recombinant antigen production as well as the ELISA methodology.¹⁴ An assay based on our protocol
91 was implemented at Mount Sinai's clinical laboratory, has received emergency use authorization from
92 New York State and is used for screening plasma donors with high titers of antibodies to SARS-CoV-2.
93 We have also distributed our protocol and reagents to well above 200 laboratories across the globe.

94

95 **Results**

96 **Expression constructs and generation of recombinant SARS-CoV-2 proteins**

97 We generated two different versions of the SARS-CoV-2 spike protein. The first construct expresses a full
98 length trimeric and stabilized version of the spike protein and the second one produces only the much
99 smaller receptor binding domain (RBD). The sequence used for both proteins is based on the genomic
100 sequence of the first virus isolate, Wuhan-Hu-1, which was released on January 10th 2020.¹ Sequences
101 were codon optimized for mammalian cell expression. The full-length spike protein sequence was
102 modified to remove the polybasic cleavage site, which is recognized by furin and to add a pair of
103 stabilizing mutations (**Figure 1**).^{7,15,16} These two modifications were included to enhance the stability of
104 the protein based on published literature.^{7,15} At amino acid P1213 the sequence was fused to a thrombin
105 cleavage site, a T4 foldon sequence for proper trimerization and a C-terminal hexahistidine tag for
106 purification (**Figure 1**).^{17,18} The sequence was cloned into a pCAGGS vector for expression in mammalian
107 cells and into a modified pFastBac Dual vector for generation of baculoviruses and expression in insect
108 cells. For expression of the RBD, the natural N-terminal signal peptide of S was fused to the RBD
109 sequence (amino acid 319 to 541) and joined with a C-terminal hexahistidine tag.¹⁹ The same vectors as
110 for the full length S protein were used to express the RBD. In mammalian cells, the RBD domain gave
111 outstanding yields (approximately 25-50 mg/liter culture), but expression was lower in insect cells
112 (approximately 1.5 mg/liter culture). Clear single bands were visible when the recombinant RBD proteins
113 were analyzed on a reducing sodium dodecyl sulfate–polyacrylamide gel electrophoresis (SDS-PAGE),
114 with the insect cell derived protein (iRBD) running slightly lower than the mammalian cell derived
115 protein (mRBD) (**Figure 1**). The size difference likely reflects differences in glycan sizes between insect
116 cells and mammalian cells. The full-length S protein was also expressed in both systems with slightly
117 higher yields in mammalian cells (mSpike) than in insect cells (iSpike) (approximately 5 mg/liter cultures
118 versus 0.5 mg/liter culture). The full-length protein appeared as prominent band between 135 and 190
119 kDa followed by a faint, second band slightly below on a reducing SDS-PAGE, the higher species likely
120 being the full-length protein and the slightly lower species likely a cleavage product.

121

122 **ELISA development**

123 Initially, we tested a panel of 50 (59 for mRBD) banked human serum samples collected from study
124 participants without and with confirmed previous viral infections (e.g., hantavirus, dengue virus,
125 coronavirus NL63 – sample take 30 days post symptom onset) to establish an ELISA with our proteins.
126 These human sera were used to test the background reactivity to the SARS-CoV-2 spike in the general US
127 population covering an age range from approximately 20 to 65+ years. An initial set of four
128 plasma/serum samples from three COVID19 survivors were used to determine the reactivity of SARS-
129 CoV-2 infected individuals to the RBD and the full length spike (**Figure 2**).

130 ELISAs were performed by doing serial dilution of the individual serum samples. Values from the dilution
131 curves were used to determine the area under the curve (AUC), which was graphed. All COVID19
132 plasma/serum samples reacted strongly to both RBD and full-length spike protein while reactivity of the
133 other serum samples only yielded background reactivity (**Figure 2**). Reactivity of COVID19 sera was, in
134 general, stronger against the full-length S protein than against the RBD, likely reflecting the higher
135 number of epitopes found on the much larger spike protein. For the RBD the difference between
136 control sera and convalescent sera was larger when the mammalian cell derived protein was used as
137 compared to the insect cell derived RBD. The same was true for the full-length spike protein. Due to the
138 expanding epidemic in New York City, we tested next an additional 14 serum samples from patients with
139 acute COVID19 disease as well as convalescent participants for reactivity to mRBD and mSpike. These
140 additional data were added to **Figure 2B, 2D, 2F and 2H**. All 14 samples reacted well with both RBD and
141 spike protein. Thus, our assays allowed to clearly distinguish the sera from participants diagnosed with
142 COVID19 from those collected prior to the pandemic (e.g., collected in the fall of 2019).

143 Our initial set of negative controls included convalescent serum from a participant with a confirmed
144 NL63 infection. Importantly, this sample did not produce a signal against the SARS-CoV-2 RBD or spike
145 underscoring the specificity of our assays. Since human coronaviruses OC43, 229E, NL63 and/or HKU1
146 are responsible for a large proportion of common colds every year, cross-reactivity between SARS-CoV-2
147 and these seasonal coronaviruses is of particular importance and warranted further investigation. To
148 test how common antibodies to human corona viruses other than SARS-CoV are in our “pre-pandemic
149 serum panel”, we performed ELISAs coated with spike protein of coronavirus 229E and NL63. While
150 none of the negative control sera reacted to SARS-CoV-2 RBD and spike, the majority of samples yielded
151 strong signals to the spike proteins of these two human coronaviruses (**Figure 2I and 2J**). In addition, we
152 tested 21 different batches (27 vials) of pools of different products of normal human immune globulin
153 (NHIG), intended for intravenous use and derived from >1000 donors each. None of the NHIG
154 preparations reacted with SARS-CoV-2 RBD or spike protein and the signal obtained was similar to that
155 of the three irrelevant human monoclonal antibodies (mAbs). The RBD-binding mAb CR3022 produced,
156 in contrast, a strong signal (**Figure 3A and 3B**).²⁰⁻²² Lastly, we tested panel of fifty plasma samples
157 collected from HIV positive patients banked 2008 and 2011. Again, none of the samples reacted with the
158 SARS-CoV-2 RBD or spike (**Figure 3C and 3D**).

159 **The assay can measure antibodies in serum and plasma as well as with and without heat inactivation**

160 One complexity with measuring antibodies in bodily fluids of COVID19 patients is, that infectious virus
161 could be present in the biospecimen, especially early during acute infection. One precaution that is,
162 therefore, often used to limit this risk is to heat inactivate serum or plasma for 1 hour at 56°C. To test if
163 such a heat treatment has an effect on detecting antibodies to the SARS-CoV2 RBD and spike, we
164 compared reactivity of matched non-treated and heat-treated serum samples. While slight differences

165 were observed, they were minimal suggesting that heat treatment has no negative impact on assay
166 performance (**Figure 4A and B**). Similarly, we tested matched serum and plasma samples from patients
167 with COVID19 and found negligible differences suggesting that both types of specimens can be used in
168 the assay interchangeably (**Figure 4C and D**).

169 **Antibody isotyping, subtyping and neutralizing activity**

170 For the four COVID19 patient plasma/sera from our initial panel, we performed an isotyping and
171 subtyping ELISA using the mammalian cell expressed S proteins. Strong reactivity was found for all
172 samples for IgG3, IgM and IgA (**Figure 5A**). An IgG1 signal was detected for the majority of samples; low
173 reactivity for IgG2 (in five samples) and IgG4 (in four samples) was also detected. Data from this
174 isotyping ELISA suggest that the IgG response is dominated by IgG3 subtype. Furthermore, we correlated
175 the ELISA reactivity with the neutralizing activity of sera against the USA-WA1/2020 isolate. ELISA titers
176 and microneutralization titers correlated significantly (**Figure 5B**) with a Spearman r of 0.9279.

177

178 **Discussion**

179 Here we describe a serological method to detect seroconversion upon SARS-CoV-2 infection with high
180 specificity and sensitivity. The method is based on reactivity to the immunogenic S protein of the virus.
181 The method is relatively simple and quick in its execution and can be performed at biosafety level 2 level
182 as it does not involve live virus. We have tested these methods using banked serum samples and NHIG
183 preparations obtained from individuals before SARS-CoV-2 started to widely circulate in the US. These
184 serum samples produced low, close to baseline signals in our ELISAs. The age range of the participants
185 was broad, ranging from 20 to 65+ years of age and it is likely that most of these individuals had
186 experienced infections with human coronaviruses including the alphacoronaviruses NL63 and 229E as
187 well as the betacoronaviruses OC43 and HKU1. In fact, the majority of our negative control subjects had
188 strong reactivity to the spike of NL63 and 229E (but showed no cross-reactivity to SARS-CoV-2 RBD and
189 spike). We also included paired serum samples (acute and convalescent) from a participant with a
190 laboratory confirmed coronavirus NL63 infection. Our data show that there is no or only negligible cross-
191 reactivity from human coronaviruses to SARS-CoV-2. Of note, even infection with the human
192 alphacoronavirus NL63, which also uses ACE2 as receptor²³, did not induce cross-reactivity. Similar
193 findings were reported in a recent preprint where sera from negative control subjects reacted well with
194 spike proteins from human coronavirus but not with SARS-CoV-2.²⁴ This is of great importance because
195 it suggests that humans are completely naïve to SARS-CoV-2, which may explain the relatively high R_0 of
196 SARS-CoV-2 compared to other respiratory viruses such as influenza virus.²⁵ It might also suggest that
197 antibody-dependent enhancement from human coronavirus induced cross-reactive antibodies targeted
198 at the S protein is unlikely to be the cause of the high pathogenicity of the virus in humans.²⁶

199 Our data show strong seroconversion after natural infection with SARS-CoV-2. Results from our assays
200 suggest that antibodies mounted upon infection target the full length S protein as well as the RBD,
201 which is the major target for neutralizing antibodies for related viruses coronaviruses.⁹ In fact, sample
202 SARS-CoV2 #1 was tested in another study in neutralization assays and showed a neutralizing titer of
203 1:160.¹³ In addition, we performed microneutralization assays with a subset of our samples and found
204 excellent correlation between our ELISA titers against the spike protein and virus neutralization. Several
205 of the sera from individuals with confirmed COVID19 showed very strong neutralizing activity with 50%

206 inhibitory concentrations in the hundreds and thousands. Thus, seroconversion might lead to protection
207 from reinfection. Of course, protection – and antibody titers correlated with protection – need to be
208 determined in the near future. In fact, studies to determine whether antibody titers correlate with
209 protection from COVID19 should be one of the highest research priorities at this time. Of note, the ELISA
210 reagents used are derived from the original sequence from Wuhan, the neutralization assays were
211 performed with USA-WA1/2020 (an Asian lineage strain) while the majority of sera were obtained from
212 subjects infected with European-lineage viruses.²⁷ The observed correlation between ELISA and
213 neutralization assays hints at minimal antigenic changes. Another interesting finding was, that the IgG3
214 response appeared stronger than the IgG1 response which is in contrast to e.g. the immune response to
215 influenza where usually IgG1 responses dominate.^{28,29} This is of interest since IgG3 has a stronger affinity
216 to activating Fc-receptors but a shorter half-life than IgG1. We also detected strong IgA and IgM
217 responses in the blood compartment. Of note, level of reactivity and antibody isotypes closely matched
218 expected patterns based on time since symptom onset very well. Antibody isotype and subtype titers
219 were determined using specific secondary antibodies and future studies; however, need to confirm this
220 finding using independent methods.

221 We also evaluated if heat inactivation can interfere with detection of antibodies. Heat inactivation at
222 56°C is a standard precaution for work with human sera in many laboratories. A recent pre-print had
223 shown that a commercial AIE/quantum dot-based fluorescence immunochromatographic assay (AFIA,
224 KingFocus Biomedical Engineering Co.,Ltd) assays failed to detect antibodies in samples treated at 56°C
225 for 30 min.³⁰ We had made similar observations with a lateral flow assay from BioMedomics. However,
226 our assay was able to detect a signal in samples heat treated for 60 min at 56°C comparable to a signal
227 obtained from non-heat treated sera. Similarly, we found that matched serum and plasma samples
228 showed similar reactivity in the ELISA making it very versatile in terms of which type of specimen can be
229 used.

230 We did not formally assess specificity and sensitivity of our assay since it might be implemented with
231 different readouts (e.g. OD at a certain dilution, AUC, endpoint titer etc.) and since the assay itself will
232 slightly vary depending on the laboratory that will implement it. However, it is clear from our data that
233 the assay has a high specificity and sensitivity. In addition, our assays are able to measure a quantitative
234 titer which correlates well with neutralization of virus. This is in contrast to many commercial assays that
235 have recently become available on the market which deliver only a qualitative result. Of note, many of
236 these assays have not been independently validated and some of them have been shown to be unfit for
237 the purpose of specifically detecting seroconversion after SARS-CoV-2 infections (e.g. in the UK; Loreda,
238 Texas etc.).

239 We believe that our ELISA method will be key for serosurveys aimed at determining the real attack rate
240 and infection fatality rate in different human populations and to map the kinetics of the antibody
241 response to SARS-CoV-2. While we found seroconversion in severe, mild and asymptomatic cases, it is
242 possible that some individuals do not seroconvert or that antibody titers wane within short periods of
243 time. To be able to interpret serosurveys correctly, studies to assess the kinetics of the antibody
244 response and the rate of non-responders are urgently needed. Clinical trials with convalescent serum as
245 therapeutic have been initiated in China (e.g. NCT04264858). In addition, a recent report suggests that
246 compassionate use of these interventions could be successful.³¹ Screening potential plasma donors for
247 high antibody titers using our assay is faster and easier than performing standard neutralization assays
248 in BSL3 containment laboratories. Our assay has already been implemented for this purpose in Mount

249 Sinai's Clinical Laboratory Improvement Amendments (CLIA) regulated clinical laboratory and has
250 received emergency use authorization from New York State. Indeed, more than 20 patients with
251 COVID19 have been compassionately treated at Mount Sinai Hospital with antibody rich plasma from
252 convalescent donors identified with our assays. Last but not least, we believe that our assays could be
253 used to screen health care workers to allow selective deployment of immune medical personnel to care
254 for patients with COVID19. Such a strategy would likely limit nosocomial spread of the virus. More
255 generally, individuals with strong antibody responses could return to normal life, something that might
256 be especially important if a second or third pandemic wave makes quarantine measures again
257 necessary. Importantly, the assumption that individuals with antibodies to the SARS-CoV-2 confer
258 protection from reinfection needs to be confirmed and studies to investigate this should be started as
259 soon as possible. Of course, the generated recombinant proteins are also excellent reagents for vaccine
260 development and can serve as baits for sorting B cells for monoclonal antibody generation. We are
261 making the methods and laboratory reagents widely available to the research community in order to
262 support the global effort to limit and mitigate spread of SARS-CoV-2. A detailed protocol¹⁴ for antigen
263 expression and ELISA set up is available from the corresponding author and plasmids and proteins have
264 so far been shared with more than 200 laboratories worldwide and also deposited at BEI Resources.

265

266 **Methods**

267 **Recombinant proteins**

268 The mammalian cell codon optimized nucleotide sequence coding for the spike protein of SARS-CoV-2
269 isolate (GenBank: MN908947.3) was synthesized commercially (GeneWiz). The receptor binding domain
270 (RBD, amino acid 319 to 541, RVQP...CVNF) along with the signal peptide (amino acid 1-14,
271 MFVF...TSGS) plus a hexahistidine tag was cloned into mammalian expression vector pCAGGS as well as
272 in a modified pFastBacDual vectors for expression in baculovirus system. The soluble version of the spike
273 protein (amino acids 1-1213, MFVF...IKWP) including a C-terminal thrombin cleavage site, T4 foldon
274 trimerization domain and hexahistidine tag was also cloned into pCAGGS. The protein sequence was
275 modified to remove the polybasic cleavage site (RRAR to A) and two stabilizing mutations were
276 introduced as well (K986P and V987P, wild type numbering). Recombinant proteins were produced
277 using the well-established baculovirus expression system and this system has been published in great
278 detail in ^{17,32,33} including a video guide. Recombinant proteins were also produced in Expi293F cells
279 (ThermoFisher) by transfections of these cells with purified DNA using ExpiFectamine 293 Transfection
280 Kit (ThermoFisher). Supernatants from transfected cells were harvested on day 3 post-transfection by
281 centrifugation of the culture at 4000 g for 20 minutes. Supernatant was then incubated with 6 mls Ni-
282 NTA agarose (Qiagen) for 1-2 hours at room temperature. Next, gravity flow columns were used to
283 collect the Ni-NTA agarose and the protein was eluted. Each protein was concentrated in Amicon
284 centrifugal units (EMD Millipore) and re-suspended in phosphate buffered saline (PBS). Proteins were
285 analyzed on reducing SDS-PAGE. The DNA sequence for all constructs is available from the Krammer
286 laboratory. Several of the expression plasmids and proteins have also been submitted to BEI Resources
287 and can be requested from their web page for free (<https://www.beiresources.org/>). S1 proteins of
288 NL63 and 229E were obtained from Sino Biologics (produced in 293HEK cells, hexa-histidine tagged). A
289 detailed protocol for protein expression of RBD and spike in mammalian cells is also available.¹⁴

290

291 **SDS-PAGE**

292 Recombinant proteins were analyzed via a standard SDS-PAGE gel to check protein integrity. One ug of
293 protein was mixed with 2X Laemmli buffer containing 5% beta-mercaptoethanol (BME) at a ratio of 1:1.
294 Samples were heated at 100 °Celsius for 15 minutes and then loaded onto a polyacrylamide gel (5% to
295 20% gradient; Bio-Rad). Gels were stained with SimplyBlue SafeStain (Invitrogen) for 1-2 hours and then
296 de-stained in distilled water overnight.

297

298 **Human samples**

299 Human plasma and serum samples were obtained from a number of different sources.

300 First, de-identified samples from the University of Melbourne (n=3, taken on day 2, 4 and 6 after
301 symptom onset) and University of Helsinki (n=1, day 20 after symptom onset, neutralizing titers 1:160)¹³
302 were used as positive controls. For those, human experimental work was conducted according to the
303 Declaration of Helsinki Principles and according to the Australian National Health and Medical Research
304 Council Code of Practice. All participants provided written informed consent prior to the study. The
305 studies were approved by the Alfred Hospital (ID #280/14) and University of Melbourne (ID #1442952.1,
306 1955465.2) Human Research Ethics Committees, and under research permit for project TYH2018322 of
307 Helsinki University Hospital Laboratory.

308 Second, banked human samples were collected from study participants enrolled in several ongoing IRB
309 approved longitudinal observational study protocols of the Mount Sinai Personalized Virology Initiative.
310 The pre-pandemic serum panel comprised samples selected based on the date of collection (e.g., fall
311 2019) and whether participants had a documented history of viral infection (e.g., dengue virus,
312 hantavirus, Chikungunya virus, coronavirus NL63). All participants agreed to sample banking and future
313 research use. Self-reported ethnicities of the individuals from which samples were tested included
314 Caucasian, Asian, African American and Hispanic. Samples included sera from a participant with acute
315 NL63 infection as determined by the Biofire Respiratory panel. We included serum collected at day 3
316 post symptom onset as well as convalescent serum from the same person (day 30 post symptom onset).
317 These samples served as negative controls given that they were collect prior to SARS-CoV-2 spread in
318 the US. Six subjects were 20-29, 19 were 30-39, 13 were 40-49, 7 were 50-59 years old and six were 60
319 or older. For the mRBD ELISAs sera from additional nine subjects were tested (30-39: 2; 40-49: 4; 50-59:
320 2; 60+: 1). The pre-pandemic panel was complemented by a collection of plasma samples collected from
321 50 HIV-1 infected individuals between 2008 and 2011.

322 The COVID19 panel comprised serum and plasma samples from individuals with severe, mild or
323 asymptomatic SARS-CoV-2 infections. Seven paired serum and plasma samples from patients with
324 COVID19 were used for comparison purposes. These samples were collected between 7 and 31 days
325 post symptom onset.

326

327 **Normal human immunoglobulin (NHIG)**

328 The following NHIG preparations, each prepared from >1000 blood/ plasma donors and intended for
329 intravenous use for medical conditions, were tested in an ELISA to determine if they have reactivity
330 against SARS-CoV-2 spike or RBD: Octagam (M934A8541), Gamunex-c (B2GMD00943, A1GLD01882,
331 B3GLD01223, A1GLD01902, B2GLD01972, B3GGD00143, A1GKE00012 (2 different vials), B2GKD00863,
332 B2GJE00033 (3 different vials)), Gammagard liquid (LE12T292AB, LE12V238AB, LE12V278AD),
333 Gammagard S/D (LE08V027AB, 4 different vials), Gammagard liquid (C19G080AAA, LE12V071AD,
334 LE12V230AB, LE12V115AC, LE12V205AB, LE12VE25AB, LE12V115AC).

335

336 **ELISA**

337 The ELISA protocol was adapted from previously established protocols^{34,35}. Ninety-six well plates
338 (Immulon 4 HBX; Thermo Scientific) were coated overnight at 4°Celsius with 50 ul per well of a 2 ug/ml
339 solution of each respective protein suspended in PBS (Gibco). The next morning, the coating solution

340 was removed and 100 ul per well of 3% non-fat milk prepared in PBS with 0.1% Tween 20 (TPBS) was
341 added to the plates at room temperature (RT) for 1 hour as blocking solution. Serum samples were
342 heated at 56°C for 1 hour before use to reduce risk from any potential residual virus in serum. Serial
343 dilutions of serum and antibody samples were prepared in 1% non-fat milk prepared in TPBS. The
344 blocking solution was removed and 100 ul of each serial dilution was added to the plates for 2 hours at
345 RT. Next, the plates were washed thrice with 250ul per well of 0.1% TPBS. Next, a 1:3000 dilution of goat
346 anti-human IgG-horseradish peroxidase (HRP) conjugated secondary antibody (ThermoFisher
347 Scientific) was prepared in 0.1% TPBS and 100 ul of this secondary antibody was added to each well for 1
348 hour. Plates were again washed thrice with 0.1% TBS. Once completely dry, 100 ul of SigmaFast OPD (*o*-
349 phenylenediamine dihydrochloride; Sigma-Aldrich) solution was added to each well. This substrate was
350 left on the plates for 10 minutes and then the reaction was stopped by addition of 50 µL per well of 3 M
351 hydrochloric acid (HCl). The optical density at 490 nanometers was measured via a Synergy 4 (BioTek)
352 plate reader. The background value was set at and optical density (OD) 490nm of 0.11 and area under
353 the curve (AUC) was calculated. AUC values below 1 were assigned a value of 0.5 for graphing and
354 calculation purposes. Data were analyzed using Prism 7 (Graphpad). In some cases endpoint titers were
355 calculated, the endpoint titer being the last dilution before reactivity dropped below and OD 490nm of
356 below 0.11. To determine the impact of heat treatments, paired samples that were heat treated or not
357 treated were analyzed. NHIGs were run similar as serum/plasma samples but with a starting dilution at a
358 concentration of 100 ug/ml. Three non-SARS-CoV-2 reactive human mAbs and CR3022²⁰⁻²², a human
359 mAb reactive to the RBD of both SARS-CoV-1 and SARS-CoV-2 were used as controls.

360 To assess the distribution of the different antibody isotypes/subclasses in the samples that reacted well
361 in our standard ELISA, another ELISA was performed with different secondary antibodies²⁹. These
362 antibodies include anti-human IgA (α-chain-specific) HRP antibody (Sigma A0295) (1:3,000), anti-human
363 IgM (µ-chain-specific) HRP antibody (Sigma A6907) (1:3,000), anti-human IgG1 Fc-HRP (Southern Biotech
364 9054-05) (1:3,000), anti-human IgG2 Fc-HRP (Southern Biotech #9060-05) (1:3,000), anti-human
365 IgG3hinge-HRP (Southern Biotech 9210-05) (1:3,000), and anti-human IgG4 Fc-HRP (Southern Biotech
366 9200-05).

367

368 **Microneutralization assay**

369 Vero.E6 cells were seeded at a density of 20,000 cells per well in a 96-well cell culture plate in cDMEM.
370 The following day, heat inactivated serum samples (dilution of 1:10) were serially diluted 3-fold in 2X
371 MEM (20% 10× minimal essential medium (Gibco), 4mM L-glutamine, 0.2% of sodium bicarbonate
372 [wt/vol; Gibco], 20mM 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES, Gibco), 200U/ml
373 penicillin–200µ/ml streptomycin (Gibco), and 0.4% bovine serum albumin (MP Biomedical)). The
374 authentic SARS-CoV-2 virus (USA-WA1/2020, GenBank: MT020880) was diluted to a concentration of
375 100 50% cell culture infectious doses (TCID₅₀) in 2xMEM. Eighty µL of each serum dilution and 80µL of
376 the virus dilution were added to a 96-well cell culture plate and allowed to incubate for 1 hr at room
377 temperature. cDMEM was removed from Vero.E6 cells and 120 µL of the virus-serum mixture was
378 added to the cells and the cells were incubated at 37°C for 1 hr. After the 1 hr incubation, the virus-
379 serum mixture was removed from the cells and 100 µL of each corresponding serum dilution and 100 µL
380 of 2X MEM containing 2% FBS (Corning) was added to the cells. The cells were incubated for 48 hr at
381 37°C and then fixed with 10% paraformaldehyde (PFA) (Polysciences, Inc) for 24 hr at 4°C. Following
382 fixation, the PFA was removed and the cells were washed with 200 µL of PBS. The cells were then
383 permeabilized by the addition of 150 µL of PBS containing 0.1% Triton X-100 for 15 minutes at room
384 temperature. The plates were then washed three times with PBS containing 0.1% Tween 20 (PBS-T) and
385 blocked in blocking solution (3% milk [American Bio] in PBS-T) for 1h at room temperature. After

386 blocking, 100 μ L of 1C7 (anti-SARS NP antibody generated in house) at a dilution of 1:1000 was added to
387 all wells and the plates were allowed to incubate for 1 hr at room temperature. Plates were then
388 washed three times with PBS-T before the addition of goat anti-mouse IgG-horseradish peroxidase (IgG-
389 HRP; Rockland Immunochemicals) (diluted 1:3000) in blocking solution for 1 hr at room temperature.
390 Plates were then washed three times with PBS-T and the *O*-phenylenediamine dihydrochloride (OPD)
391 substrate (SigmaFast OPD; Sigma-Aldrich) was added. After a 10-minute room temperature incubation,
392 the reaction was stopped by adding 50 μ L of 3M HCl to the mixture. The optical density (OD) was
393 measured at 490 nm on a Synergy 4 plate reader (BioTek). A cutoff value of the average of the OD
394 values of blank wells plus three standard deviations was established for each plate and used for
395 calculating the microneutralization titer.
396

397 **Statistical analysis**

398 Differences between negative controls and positive controls were analyzed using an unpaired t-test.
399 Differences between paired non-treated and heat-treated samples as well as paired serum and plasma
400 samples were analyzed using a paired t-test. Correlation between ELISA titers and neutralization titers
401 were analyzed using Spearman's rank test. Analyses were performed in GraphPad Prism.
402

403 **Acknowledgements**

404 We would like to thank Yong-Zhen Zhang (Fudan University) and Eddie Holmes (University of Sydney) for
405 sharing the sequence of the first SARS-CoV-2 isolate in a very timely manner. We thank Jill Garlick and
406 Janine Roney (Alfred Hospital, Melbourne) for data and specimen collection and Nouran Aboelregal for
407 making lots of different NHIGs products (Mount Sinai) available. We are also thankful to Genewiz for
408 speeding up gene synthesis for this project, and being very accommodating to our needs. Furthermore,
409 we want to thank Donna Tidmore for help with ordering primers with near light speed and and finally
410 Susie (Changsu) Dong for commuting to New Jersey on several occasions to pick up reagents from
411 Genewiz. We also thank the study participants for providing biospecimen for research purposes and the
412 Conduits: Mount Sinai Health System Translational Science Hub (NIH grant U54TR001433) for supporting
413 sample collection. The work of the Personalized Virology Initiative is supported by institutional funds
414 and philanthropic donations. This work was partially supported by the NIAID Centers of Excellence for
415 Influenza Research and Surveillance (CEIRS) contract HHSN272201400008C, the Australian National
416 Health and Medical Research Council (NHMRC) NHMRC Program Grant (1071916) and NHMRC Research
417 Fellowship Level B (#1102792), the Academy of Finland and Helsinki University Hospital Funds
418 (TYH2018322). Furthermore, we thank our generous community for providing essential funds and
419 support for our SARS-CoV-2 and COVID-19 research efforts. The following reagent was deposited by the
420 Centers for Disease Control and Prevention and obtained through BEI Resources, NIAID, NIH: SARS-
421 Related Coronavirus 2, Isolate USA-WA1/2020, NR-52281. Finally, we want to thank all the study
422 participants for their contribution to research. We wish the patients with COVID19 a speedy recovery.

423 **Data availability statement**

424 The data shown in the manuscript is available upon request from the corresponding author.

425 **Conflict of interest**

426 Mount Sinai is in the process of licensing out assays based on the assays described here to commercial
427 entities.

509 **Figure 1: Constructs for recombinant protein expression. A** Visualization of the trimeric spike protein of
510 SARS-CoV-2 based on PBD # 6VXX using Pymol.⁸ One monomer is colored in dark blue while the
511 remaining two monomers are held in light blue. The receptor binding domain (RBD) of the dark blue
512 trimer is highlighted in red. **B** Schematic of the wild type full length spike protein with signal peptide,
513 ectodomain, receptor binding domain, furin cleavage site, S1, S2, and transmembrane and endodomain
514 domain indicated. **C** Schematic of the soluble trimeric spike. The polybasic/furin cleavage site (RRAR)
515 was replaced by a single A. The transmembrane and endodomain were replaced by a furin cleavage site,
516 a T4 foldon tetramerization domain and a hexahistidine tag. Introduction of K986P and V987P has been

517 shown to stabilize the trimer in the pre-fusion conformation. **D** Schematic of the soluble receptor
518 binding domain construct. All constructs are to scale. **E** Reducing SDS PAGE of insect cell and mammalian
519 cell derived soluble trimerized spike protein (iSpike and mSpike). **F** Reducing SDS PAGE of insect cell
520 derived and mammalian cell derived recombinant receptor binding domain (iRBD and mRBD).

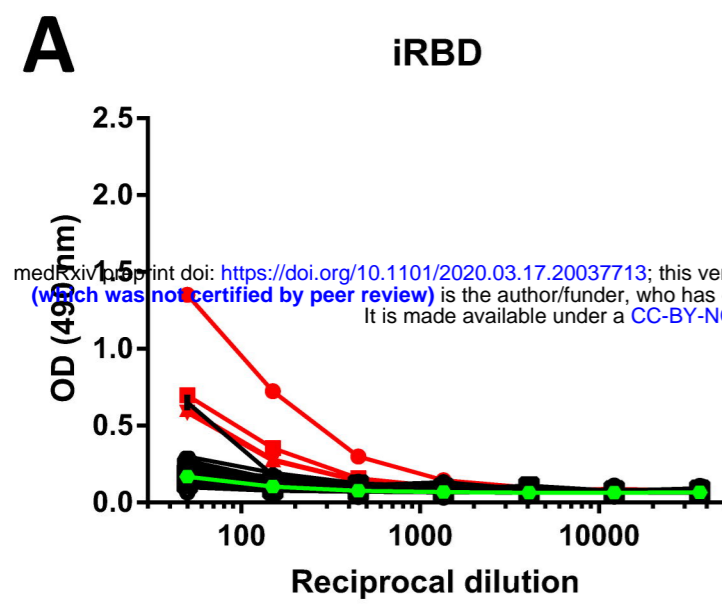

521 **Figure 2: Reactivity of control and SARS-CoV-2 convalescent sera to different spike antigens. A-D**
522 Reactivity to insect cell derived RBD (iRBD), mammalian cell derived RBD (mRBD), insect cell derived
523 soluble spike protein (iSpike) and mammalian cell derived soluble spike protein (mSpike). Sera from
524 SARS-CoV-2 infected individuals are shown in red. One sample, shown in green, is a convalescent serum
525 sample post NL63 infection. **E-F** shows data from the same experiment but graphed as area under the
526 curve (AUC) to get a better quantitative impression. The n for the control samples is 50 except for the
527 iRBD where it is 59. Statistics were performed using an unpaired two-tailed student's t-test in Graphpad
528 Prism. **I-G** shows reactivity of the 50 negative control samples from A-F against spike protein from
529 human coronaviruses 229E and NL63.

530 **Figure 3: Human normal immunoglobulin preparations and historic sera from HIV+ patients**
531 **do not react with the SAR-CoV-2 spike. A-B** Reactivity of 21 different pools of human normal
532 immunoglobulin (HNIG) preparations (27 different vials) to mRBD and mSpike of SARS-CoV-2. MAb
533 CR3022 was used as positive control, three different irrelevant human mAbs were used as negative
534 control. **C-D** shows reactivity of historic samples from 50 HIV+ individuals to mRBD and mSpike of SARS-
535 CoV-2. Both HNIG and serum samples from HIV+ donors were collected before the SARS-CoV-2
536 pandemic.

537 **Figure 4: Effect of heat treatment and serum versus plasma on assay performance. A-B** Reactivity of
538 paired non-treated serum and heat treated serum samples to mRBD and mSpike of SARS-CoV-2 (n=5). **C-**
539 **D** Reactivity of paired serum and plasma samples to mRBD and mSpike of SARS-CoV-2 (n=7). Statistics
540 were performed using a paired student's t-test in Graphpad Prism.

541 **Figure 5: Isotypes and subtypes of antibodies from COVID19 patients to the soluble spike protein and**
542 **correlation between ELISA and microneutralization titer. (A)** Mammalian cell derived spike protein was
543 used to study isotype/subclass distribution of antibodies (n=13 positive samples). **(B)** Correlation
544 between ELISA titers and microneutralization titers (n=12, the three samples from negative control sera
545 overlap and are displayed as single point). Statistics were performed using Pearson's rank test in
546 Graphpad Prism.
