National Diabetes Awareness Month — November 2005

In 2005, an estimated 20.8 million persons in the United States, approximately 7% of the population, have diabetes; however, only 14.6 million of these persons have had the disease diagnosed (*1*). Persons with diabetes have a risk for premature death approximately twice that of persons of similar ages without diabetes. In 2002, diabetes was the sixth leading cause of death in the United States, with associated direct and indirect costs totaling an estimated $132 billion (*1*).

November is National Diabetes Awareness Month; throughout the month, *MMWR* will publish reports on diabetes. CDC is working in conjunction with the 50 states, eight territories, and the District of Columbia to reach populations at greatest risk for diabetes, including American Indians/Alaska Natives (AI/ANs) and Hispanics. AI/ANs are 2.2 times more likely to have diabetes than non-Hispanic whites of similar ages (*1*). The CDC Native Diabetes Wellness Program is developing books to teach children and parents about healthy eating and physical activity, two important factors in diabetes prevention. In addition, the CDC National Diabetes Education Program is working with a Spanish-language television network to introduce a diabetes prevention and care theme into a telenovela (serial drama). Additional information about diabetes is available from CDC at http://www.cdc.gov/diabetes.

Incidence of End-Stage Renal Disease Among Persons With Diabetes — United States, 1990–2002

Diabetes mellitus is the leading cause of end-stage renal disease (ESRD) (i.e., kidney failure requiring dialysis or transplantation) in the United States, accounting for 44% of new cases of treated ESRD in 2002 (*1*). To examine trends in ESRD attributed to diabetes mellitus (ESRD-DM) in the United States, CDC analyzed 1990–2002 data from the United States Renal Data System (USRDS) and the National Health Interview Survey (NHIS). This report summarizes the findings of that analysis, which indicated that, although the number of new cases of ESRD-DM increased overall, the incidence of ESRD-DM among persons with diabetes is not increasing among blacks,* Hispanics, men, and persons aged 65–74 years, and is declining among persons aged <65 years, women, and whites. Continued interventions to reduce the prevalence of risk factors for kidney disease and improve diabetes care are needed to sustain and improve these trends.

USRDS, which is funded by the National Institute of Diabetes and Digestive and Kidney Diseases of the National

*For this report, race and ethnicity were considered independently. The only racial populations considered were black and white; persons who identified themselves as black or white might be Hispanic or non-Hispanic. Persons who identified themselves as Hispanic might be of any race.

Institutes of Health (NIH), collects, analyzes, and distributes information from clinical and claims data reports to the Centers for Medicare and Medicaid Services (CMS) regarding patients being treated for ESRD. With the ESRD entitlement program, the CMS Medicare program reimburses most of the total cost of ESRD treatment in the United States (*1*). USRDS collects demographic data and ESRD-related information, such as the date patients were first treated and the primary cause of their renal failure. CDC determined the number of persons who began treatment (i.e., dialysis or kidney transplantation) for ESRD in the United States during 1990–2002 for whom diabetes was the primary cause of renal failure. Incidence was calculated from 3-year moving averages of the annual number of U.S. residents with diabetes, as estimated by NHIS data for a weighted sample of the civilian noninstitutionalized population and age-adjusted on the basis of the 2000 U.S. standard population. In 1996, the NHIS estimate of the number of U.S. residents with diabetes was unusually low[†] (*2*), resulting in ESRD-DM incidence that was higher than expected. Beginning in 1997, data on Hispanics were collected, and the NHIS survey methodology was changed; instead of asking a one-sixth subsample of respondents whether (during the preceding 12 months) a family member had diabetes, all respondents were asked whether a health professional had ever told them they had diabetes (*3*). All analyses were conducted using statistical analysis software to account for the complex NHIS survey design. Regression analyses of annual data were used to test for trends; these analyses were performed both with and without the 1996 data.

The number of persons who began treatment for ESRD-DM increased 162%, from 16,649 in 1990 to 43,638 in 2002 (Figure 1). The age-adjusted incidence of ESRD-DM increased from 247 per 100,000 persons with diabetes in 1990 to 305 in 1996, before declining 21%, from 293 in 1997 to 232 in 2002 ($p<0.01$) (Figure 1). However, the magnitude of this decline in ESRD-DM incidence varied by age group (Figure 2). During 1997–2002, incidence decreased for persons aged <65 years (by 28% for those aged <45 years [$p<0.01$] and by 19% for those aged 45–64 years [$p<0.05$]); however, incidence did not change significantly for those aged 65–74 years, and increased 10% for those aged ≥75 years ($p<0.05$).

The magnitude of change in ESRD-DM incidence also differed by sex and by race/ethnicity (Figure 3). During 1990–2002, age-adjusted ESRD-DM incidence was greater among men than women and higher among blacks than whites. During 1997–2002, age-adjusted ESRD-DM incidence decreased

[†] Relative to 1995, the 1996 NHIS sample size was reduced by approximately 25% in the first and second quarters and by approximately 50% in the third and fourth quarters.

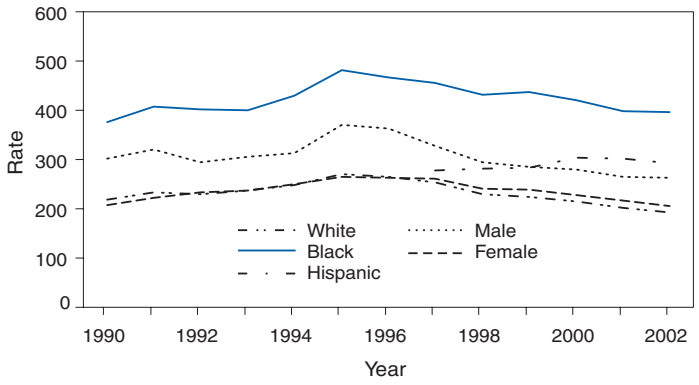
Editorial Note: ESRD is a costly and disabling condition that disproportionately affects racial/ethnic minority populations

FIGURE 3. Age-adjusted rate* of end-stage renal disease associated with diabetes mellitus among persons with diabetes, by sex and race/ethnicity† — United States Renal Data System, 1990–2002



* Per 100,000 persons with diabetes, age-adjusted on the basis of the 2000 U.S. standard population.
† Race and ethnicity were considered independently. The only racial populations considered were black and white; persons who identified themselves as black or white might be Hispanic or non-Hispanic. Persons who identified themselves as Hispanic might be of any race.

and is associated with a high mortality rate (*1*). Risk factors for ESRD-DM include familial and genetic factors, the length of time a person has had diabetes, and hyperglycemia, hypertension, and hyperlipidemia (*4*). The findings in this report indicate encouraging trends in ESRD-DM incidence. After increasing from 1990 to 1996, ESRD-DM incidence decreased during 1997–2002 among persons aged <65 years, women, and whites; stopped increasing among persons aged 65–74 years, men, and blacks; and remained level among Hispanics. The reasons for improvement cannot be determined from these surveillance data; however, they might include a reduction in the prevalence of cardiovascular disease risk factors such as high blood pressure and high cholesterol (*5*), improvements in diabetes care practices (*6*), or development of new pharmacologic agents to reduce the prevalence of kidney disease risk factors (*7*). Continued interventions (e.g., blood sugar and blood pressure control [*8–10*]) to reduce the prevalence of these risk factors and improve care among persons with diabetes are needed to sustain and improve trends in ESRD-DM incidence.

During 1997–2002, ESRD-DM incidence among men, blacks, persons aged 65–74 years, and Hispanics did not decrease as it did among certain other populations; among persons aged ≥75 years, ESRD-DM incidence increased during 1990–2002. Additional strategies are needed to reduce these disparities. Reducing incidence of ESRD-DM among persons aged ≥75 years likely will be difficult because persons with diabetes are surviving longer and ESRD typically occurs

15–20 years after onset of diabetes (*4*). Moreover, the number of ESRD cases in the United States is likely to continue to increase as the U.S. population ages and the number of persons with diabetes continues to increase. The downward trend in ESRD incidence in the population with diabetes might reverse if persons have diabetes at younger ages or live with the disease for a longer time, thus increasing their risk for developing ESRD.

The findings in this report are subject to at least four limitations. First, data were collected for patients whose ESRD treatment was reported to CMS and do not include patients who died from ESRD before receiving treatment, persons who refused treatment, or patients whose treatment was not reported to CMS. Second, the 1996 NHIS estimate of the number of U.S. residents with diabetes was unusually low (*2*); however, exclusion of 1996 data did not substantially affect incidence trends. Third, because incidence of ESRD-DM was defined as the percentage of persons with diabetes who began ESRD treatment in a given year, changes in incidence might have been caused by other factors, such as changes in diabetes treatment and care practices, greater recognition of the etiologic role of diabetes in ESRD, changes in access to treatment or acceptance of ESRD treatment, or a combination of these factors. Finally, the correlation between the length of time diabetes patients had the disease and their risk for developing ESRD-DM was not assessed because of a lack of data on duration of diabetes.

CDC provides resources and technical assistance to state and territorial diabetes-control programs to help them 1) educate persons regarding diabetes, 2) improve and monitor the quality of diabetes care, and 3) promote early detection of diabetic complications. The National Diabetes Education Program (NDEP), sponsored by CDC and NIH, aims to educate the public about controlling diabetes and preventing its complications. The NDEP campaign, "Know your ABCs,"[§] addresses risk factors for ESRD-DM, such as hyperglycemia, hypertension, and hyperlipidemia. In addition, the National Kidney Disease Education Program,[¶] sponsored by NIH, seeks to raise public awareness about the seriousness of kidney disease, the importance of testing for kidney disease among those at risk, and the availability of treatment to prevent or slow kidney failure. Similarly, the National Kidney Foundation offers the Kidney Early Evaluation Program,[**] a free health-screening program for persons at increased risk for kidney disease.

CDC will continue to work with public and private partners to reduce rates of diabetes and other risk factors for kidney disease and to improve care for persons with diabetes. Continued surveillance of ESRD-DM, its risk factors, and the level of care received by patients with diabetes will help public health officials monitor and assess progress in reducing the incidence of this serious complication of diabetes.

Global Measles and Rubella Laboratory Network, January 2004–June 2005

Measles continues to be a leading cause of childhood morbidity and mortality in developing countries and an outbreak threat in the majority of countries. In 2000, measles was considered the fifth leading cause of childhood mortality, and the World Health Organization (WHO) estimated that approximately 777,000 measles-associated deaths occurred worldwide. In 2001, WHO and the United Nations Children's Fund (UNICEF) developed a 5-year strategic plan, endorsed by the World Health Assembly in 2003, to reduce measles mortality

by 50% by 2005 (relative to 1999 estimates) and to achieve and maintain interruption of indigenous measles transmission in large geographic areas with established measles elimination goals. This plan included strengthening routine vaccination coverage, providing a second opportunity for measles immunization to children, improving measles case management, and improving surveillance with laboratory confirmation of suspected measles cases (*1*). To date, four of six WHO regions have established measles elimination targets: the Americas Region (AMR) by 2000, the European Region (EUR) by 2010, the Eastern Mediterranean Region (EMR) by 2010, and the Western Pacific Region (WPR) by 2012. The remaining two WHO regions, the African (AFR) and South East Asian (SEAR) regions, are continuing work toward the measles mortality reduction goal. Likewise, to reduce the burden of disease from congenital rubella syndrome (CRS), currently estimated at 100,000 cases per year worldwide, several countries have developed or continue to develop rubella control programs, and AMR and EUR have established regional rubella elimination and CRS reduction goals, respectively. Because improved global surveillance is essential for monitoring progress toward mortality reduction and elimination of these diseases, WHO established the Measles and Rubella Laboratory Network (LabNet) in 2003 to promote case identification and confirmation. This report provides an update on the development of LabNet during January 2004–June 2005 and describes the geographic distribution of measles and rubella virus genotypes as of June 2005.

LabNet

On the basis of the model provided by the WHO Polio Laboratory Network, WHO established the Global Measles Laboratory Network (GMLN) in 2000 to 1) provide laboratory confirmation of initial measles cases during outbreaks, 2) collect baseline measles genotype information on the regional distribution of circulating viruses useful in establishing transmission pathways of disease spread, and 3) monitor the success of vaccination campaigns and the integrity of elimination programs (*2*). Because of the similar nature of clinical surveillance and diagnostic assay procedures, GMLN also provided diagnostic support for rubella control programs and has since evolved into LabNet.

Clinical recognition of cases has low positive predictive value when the incidence of measles and rubella is low. Thus, LabNet selected highly sensitive and specific, commercially available, IgM enzyme immunoassays (EIAs) for laboratory confirmation of suspected cases of measles and rubella. LabNet includes IgM testing laboratories serving 162 countries and is still expanding. A total of 705 laboratories participate in the network, which consists of three global specialized laboratories, 16 regional reference laboratories, 178 national laboratories, and 508 subnational laboratories. More than 86,000 serum samples were tested for IgM for measles and rubella in 2004, often meeting result-reporting targets of at least 80% within 7 days of receiving the sample (Table).

The network has expanded in all WHO regions since 2003 but particularly in the WPR and AFR regions. In September 2005, WPR adopted the goal of measles elimination, with strengthening of laboratory testing as a key component of its measles surveillance strategy. AFR has implemented strategies for measles mortality reduction and has established laboratory-based surveillance before, or at times coincident with, countries beginning measles supplementary immunization activities. Thirty-six of 46 AFR countries have established measles laboratories as part of LabNet, with staff who have received training from regional or global laboratories. LabNet has been developed with a long-term objective of responsiveness to developing public health priorities in the WHO regions. For example, the laboratory network established in AMR supports 1) pursuing regional elimination goals for rubella and CRS and 2) continuing case-based investigations of measles now that elimination of indigenous measles from the region has been achieved.

Performance Monitoring

A comprehensive system for monitoring indicators of laboratory performance, including proficiency testing and annual laboratory accreditation by WHO and/or regional laboratories, has been implemented in all regions. Six quality indicators* are monitored during the 12-month review period, and a comprehensive onsite review of laboratory activities, procedures, and communication links is performed every 2–3 years. All regions have begun this process, with priority given to regions with a high burden of measles, such as AFR, SEAR, and EMR. Sixty-two (43%) of 144 national and regional reference laboratories in these three regions have been assessed, with only one failing to receive accreditation.

The IgM proficiency testing program is in its fifth year, and more than 160 panels of 20 sera will be distributed in 2005. Analysis of the 2004 measles proficiency panel resulted in 90% of 100 national laboratories achieving the pass score of at least 90%. Laboratories that fail the test are visited by WHO laboratory program officials. Problems usually are identified rapidly, deficiencies are corrected, and the laboratories are permitted to attempt the proficiency tests again.

Alternative Specimen Collection

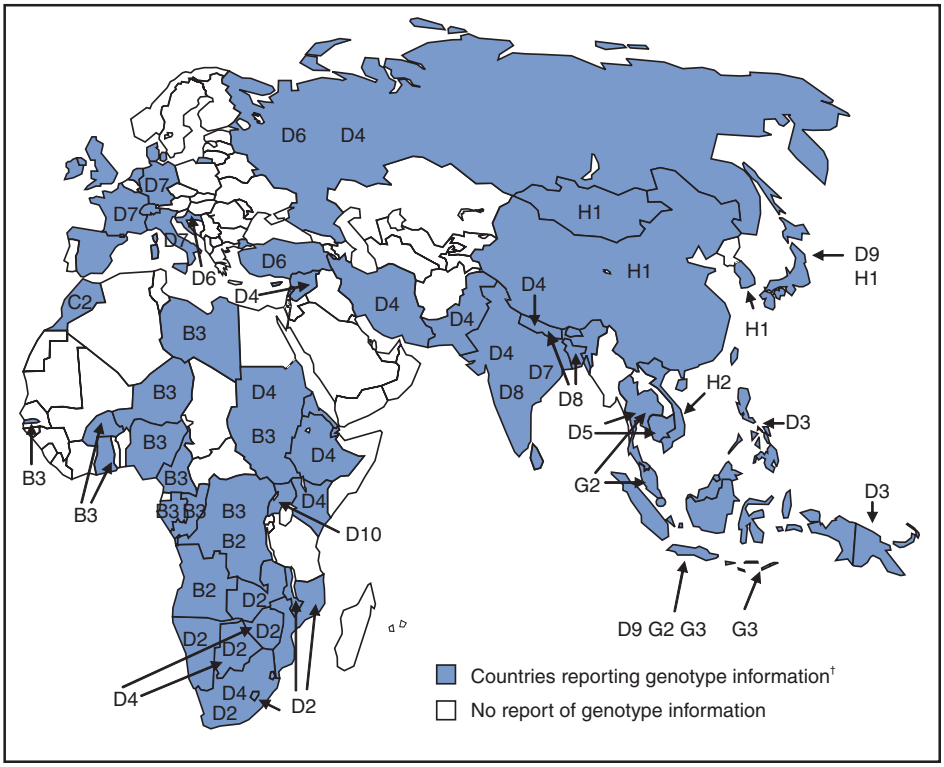
LabNet is active in developing new techniques to improve laboratory surveillance. Dried blood and oral fluid samples as an alternative to serum have been evaluated recently for measles and rubella testing. These sampling techniques might be useful when countries have difficulty in collecting venepuncture blood from infants or transporting samples under conditions of reverse cold chain to a testing laboratory. Good concordance of both oral fluid and dried blood samples with parallel serum samples was documented for measles using commercially available assays (WHO, unpublished data, 2005); however, limited data are available for rubella. IgM in dried blood and oral fluid is stable at (68°F [20°C]) for up to 1 week; however, additional data are needed regarding stability at higher temperatures.

Virus Characterization

Because molecular epidemiologic techniques provide an important tool for tracking viral transmission pathways, LabNet also supports genetic characterization of currently circulating strains of measles and rubella viruses. LabNet has standardized the nomenclature and laboratory procedures used to describe the genetic characteristics of wild-type measles (*3–6*) and rubella viruses (*7,8*); these protocols are included in all WHO-sponsored laboratory training courses. This standardization has allowed sharing of virologic surveillance data among laboratories and permitted efficient communication of these data throughout the measles and rubella control programs.

WHO currently recognizes 23 genotypes of measles virus. Although virologic surveillance for measles is still incomplete, a pattern for the global distribution of genotypes within disease-endemic regions is emerging (Figure 1). In countries

FIGURE 1. Geographic distribution of measles virus genotypes for regions that have not yet eliminated measles transmission,* 1995–2005



* The countries in the western hemisphere and Australia have eliminated measles and are not shown.
† In western Europe, genotype D7 was the most commonly reported genotype. Australia, Spain, the United Kingdom, and the countries of the western hemisphere have reported multiple genotypes attributed to importation.

* Annual accreditation requires meeting the following six criteria: 1) test results are reported on at least 80% of received samples within 7 days of receipt, 2) serologic/reverse-transcriptase polymerase chain reaction (RT-PCR) tests are performed on at least 100 specimens annually, 3) accuracy of diagnostic assays for measles and rubella IgM or RT-PCR identification is at least 90%, 4) internal quality control procedures for IgM assays are in place, 5) proficiency test score of at least 90% on WHO-distributed serum panel is achieved, and 6) the score from the annual onsite review of laboratory operating procedures and practices is at least 80%.

that have not yet interrupted measles transmission, the sequence analysis of measles isolates has revealed a limited geographic distribution of genotypes, whereas in countries that have eliminated measles, several genotypes have been detected in association with limited outbreaks, reflecting the various imported sources of these viruses.

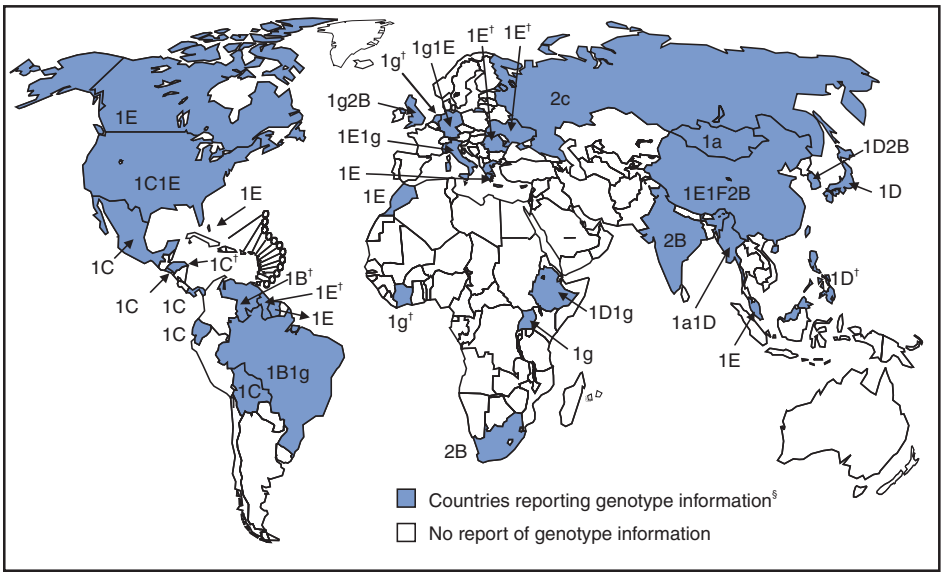
The systematic nomenclature for wild-type rubella viruses developed in 2004 and 2005 is an important advance in virologic surveillance for rubella. Seven genotypes and three additional provisional genotypes of rubella virus are recognized by WHO (Figure 2). These genotypes are classified into two clades (i.e., groups of similar genotypes), designated 1 and 2; clade 2 viruses have not been found circulating in the western hemisphere. Although knowledge concerning the geographic distribution of rubella genotypes has progressed substantially since 2003, the genotypes of rubella viruses present in many countries and regions remain unknown. LabNet encourages the collection and storage of viruses for genetic characterization.

Reported by: *PA Rota, PhD, JP Icenogle, PhD, JS Rota, MPH, WJ Bellini, PhD, Div of Viral and Rickettsial Diseases, National Center for Infectious Diseases, CDC.*

Editorial Note: Measles and rubella elimination and control programs depend on effective global surveillance. LabNet promotes case identification and confirmation, thus improving the quality of disease surveillance and furthering progress toward elimination of these diseases. The development of LabNet has progressed rapidly during the past 5 years. More than 190 national and regional reference laboratories have been equipped and trained to perform IgM ELISA procedures, and the number of measles serum samples tested in 2004 has increased 32% compared with 2003. Many countries have taken the opportunity to use this capability and expand their laboratory-based surveillance by testing for diseases endemic in their respective regions that have similar clinical features (e.g., dengue, parvovirus B19, and HHV-6) or where similar diagnostic assays might be used (e.g., yellow fever and Japanese encephalitis). Virologic surveillance data, when analyzed in conjunction with standard epidemiologic data, can help document viral transmission pathways and aid in case classification. If baseline information regarding circulating genotypes is available, molecular epidemiologic data can also help to document the elimination of endemic transmission and, therefore, provide a means to measure the effectiveness of control programs. Virologic surveillance has provided evidence of the interruption of endemic transmission of measles virus in the western hemisphere (*9*) and rubella virus in the United States (*10*). However, epidemiologic and molecular surveillance activities, coupled with active vaccination programs, must be continued as long as the threat of disease importation exists.

As new laboratories are established, surveillance improves, and laboratory workloads increase, important challenges remain in maintaining quality and meeting the resource needs of the measles and rubella LabNet. These challenges include identifying funding resources for laboratory supplies for measles and rubella testing and encouraging countries to integrate these costs into national surveillance budgets whenever possible. In addition, partners must pursue a means of 1) gaining access to data from laboratories in countries with extensive private laboratory structures for measles and/or rubella surveillance and 2) expanding the quality-assurance program for all laboratories within LabNet, including those at the subnational level.[†]

FIGURE 2. Geographic distribution of rubella virus genotypes — worldwide, 1995–2005*



* Genotype data represent a summary of information from several laboratories that was made available in July 2005.
† Viruses were characterized after importation into another country.
§ Certain countries reduced indigenous rubella to low levels or have eliminated it during this period (e.g., Canada, Cuba, the United Kingdom, and the United States).

Update: *Ralstonia* Species Associated with Vapotherm Oxygen Delivery Devices — United States, 2005

This report updates information on *Ralstonia* species associated with Vapotherm™ oxygen delivery devices (Vapotherm Inc., Stevensville, Maryland) (*1*). CDC has obtained new information from a test developed by CDC and performed by The Children's Hospital of Philadelphia (Pennsylvania) to assess the efficacy of the new chlorine dioxide disinfection protocol recommended by Vapotherm. Although limited, this information suggests that the new protocol for disinfecting Vapotherm devices and cartridges might not achieve sustained bacterial control in certain situations. At this time, the optimal protocol to disinfect machines and cartridges that might contain very heavy biofilms is not known.

Before development of the new disinfection protocol in October 2005, certain institutions had reported no growth of *Ralstonia* spp. in samples obtained from machines and cartridges disinfected according to the previous protocol. In addition, in an experiment conducted by an independent laboratory contracted by Vapotherm, a laboratory-generated biofilm (consisting of a mix of organisms) was grown in a Vapotherm device and cartridge for 3 weeks. The device and cartridge were then subjected to the new chlorine dioxide disinfection protocol. Results from this trial revealed no growth during the 4 days after disinfection.

However, in a single trial designed by CDC and involving one machine, The Children's Hospital of Philadelphia subjected a Vapotherm device and used filter cartridge to the new chlorine dioxide disinfection protocol. The device and cartridge were known to be contaminated with *Ralstonia* spp., and the unit had been out of service and not disinfected for multiple weeks. Samples obtained immediately after disinfection grew no organisms. The trial was initially designed to run for 30 days; however, after 7 days of continuous operation of the unit with no patient contact, samples from both the vapor condensate and the filter cartridge grew *Ralstonia* spp. in culture at CDC.

Whether the presence of an unusually heavy biofilm in the machine and cartridge in the hospital experiment resulted in the failure to eradicate *Ralstonia* spp. is unknown. Similarly, the impact of testing a laboratory-generated biofilm instead of a use-generated biofilm is not known. The varying results achieved with the new disinfection protocol might indicate that its efficacy depends on the maturity of any biofilm contained within Vapotherm machines or cartridges.

Testing is being conducted by a private laboratory and CDC to further assess the efficacy of and possible improvements to the new disinfection protocol; CDC continues to search for the source of *Ralstonia* spp. contamination in Vapotherm devices. Clinicians should continue to weigh the potential risks for *Ralstonia* spp. contamination of Vapotherm devices against the benefits of using the device in patients requiring humidified oxygen therapy.

Clinicians are encouraged to report findings of *Ralstonia* spp. in patients using any Vapotherm 2000 respiratory gas administration device directly to the device manufacturer, local or state health departments, or CDC by telephone, 800-893-0485. Cases or any other adverse events related to medical devices should be reported to MedWatch, the Food and Drug Administration's voluntary reporting program online at http://www.accessdata.fda.gov/scripts/medwatch; by telephone, 800-FDA-1088; by fax, 800-FDA-0178; or by mail, MedWatch, Food and Drug Administration, HF-2, 5600 Fishers Lane, Rockville, MD 20857.

Reported by: *The Children's Hospital of Philadelphia, Pennsylvania. Div of Healthcare Quality Promotion, National Center for Infectious Diseases, CDC.*

Update: West Nile Virus Activity — United States, 2005

This report summarizes West Nile virus (WNV) surveillance data reported to CDC through ArboNET as of 3 a.m. Mountain Standard Time, November 1, 2005.

Forty-two states have reported 2,581 cases of human WNV illness in 2005 (Figure and Table 1). By comparison, a total of 2,241 WNV cases had been reported as of November 2, 2004 (Table 2). A total of 1,359 (56%) of the 2,419 cases for which such data were available in 2005 occurred in males; the median age of patients was 51 years (range: 3 months–98 years). Dates of illness onset ranged from January 2 to October 21; a total of 83 cases were fatal.

A total of 374 presumptive West Nile viremic blood donors (PVDs) have been reported to ArboNET during 2005. Of these, 87 were reported from California; 57 from Texas; 53 from Nebraska; 22 from Louisiana; 20 from Arizona; 19 from Kansas; 17 from Iowa; 16 from South Dakota; 13 from Oklahoma; 11 from Minnesota; 10 from Illinois; five each from Michigan, New Mexico, and North Dakota; four each from Alabama, Pennsylvania, and Utah; three each from Nevada and Wisconsin; two each from Colorado, Indiana, Mississippi, Montana, and Ohio; and one each from Idaho, Kentucky,

TABLE 2. Comparison of human cases and deaths from West Nile virus — United States, 2002–2005

Year	Human cases	Deaths
2002*	3,419	180
2003†	7,718	166
2004§	2,241	76
2005¶	2,581	83

* As of October 30, 2002.
† As of October 29, 2003.
§ As of November 2, 2004.
¶ As of November 1, 2005.

Missouri, New York, North Carolina, and Oregon. Of the 374 PVDs, three persons aged 53, 56, and 72 years subsequently had neuroinvasive illness; seven persons (median age: 41 years [range: 17–64 years]) subsequently had other illnesses; and 82 persons (median age: 46 years [range: 17–78 years]) subsequently had West Nile fever.

In addition, 4,179 dead corvids and 892 other dead birds with WNV infection have been reported from 45 states. WNV infections have been reported in horses in 34 states; five dogs in Idaho, Minnesota, and Nebraska; six squirrels in Arizona; and five unidentified animal species in four states (Arizona, Illinois, North Carolina, and Texas). WNV seroconversions have been reported in 1,365 sentinel chicken flocks from 16 states. Eight seropositive sentinel birds have been reported in Michigan. One seropositive sentinel horse was reported in Minnesota. A total of 11,061 WNV-positive mosquito pools have been reported from 43 states and the District of Columbia.

Additional information about national WNV activity is available from CDC at http://www.cdc.gov/ncidod/dvbid/westnile/index.htm and at http://westnilemaps.usgs.gov.

Notice to Readers

Availability of Maxi-Vac Alternative

Maxi-Vac Alternative, a public use software program, is now available. Maxi-Vac Alternative was developed by CDC to help public health officials plan smallpox vaccination clinics in the event of a bioterrorist attack. Maxi-Vac Alternative allows planners to refine human resource allocations (e.g., physicians and nurses) at clinics, with the goal of maximizing patient flow-through. Maxi-Vac Alternative is a companion program to Maxi-Vac 1.0, which was released in 2003. The two programs differ in terms of the time patients will require at each station (e.g., pre-vaccination screening and vaccination) and the selections the user can make for number of personnel, size of patient pre-vaccination orientation rooms, and the need for vaccination witnesses. Because no one scenario can describe all contingencies of an emergency mass smallpox vaccination campaign, users should examine both versions before deciding which version to use.

Both Maxi-Vac Alternative and Maxi-Vac 1.0 and their manuals can be downloaded from http://www.bt.cdc.gov/agent/smallpox/vaccination/maxi-vac. Both programs and manuals are in the public domain and may be used and copied without permission; however, citation as to source (provided in the manuals and in online help functions) is appreciated.

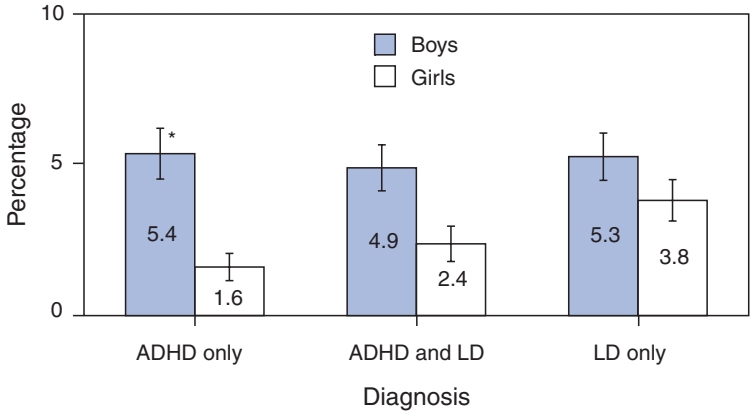
Erratum: Vol. 54, No. 40

In the *Recommended Adult Immunization Schedule — United States, October 2005–September 2006*, on page Q4, an error occurred in the first sentence under footnote 10, "Selected conditions for which *Haemophilus influenzae* type b (Hib) vaccine may be used." The sentence should read as follows: "Hib conjugate vaccines are licensed for children aged **6 weeks**–71 months."

QuickStats

FROM THE NATIONAL CENTER FOR HEALTH STATISTICS

Percentage of Children Aged 5–17 Years Ever Having Diagnoses of Attention Deficit/Hyperactivity Disorder (ADHD) or Learning Disability (LD), by Sex and Diagnosis — United States, 2003



* 95% confidence interval.

In 2003, approximately 16% of boys and 8% of girls aged 5–17 years had ever had diagnoses of ADHD or LD, according to parental reports. Boys were three times more likely than girls to have diagnoses of ADHD without LD. Boys were also more likely than girls to have LD diagnosed, either with or without ADHD.

U: Unavailable. —: No reported cases.

*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

†Pneumonia and influenza.

§Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

¶Because of Hurricane Katrina, weekly reporting of deaths has been temporarily disrupted.

**Total includes unknown ages.

The *Morbidity and Mortality Weekly Report (MMWR)* Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy each week, send an e-mail message to *listserv@listserv.cdc.gov*. The body content should read *SUBscribe mmwr-toc*. Electronic copy also is available from CDC's World-Wide Web server at *http://www.cdc.gov/mmwr* or from CDC's file transfer protocol server at *ftp://ftp.cdc.gov/pub/publications/mmwr*. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone 202-512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the *MMWR* Series, including material to be considered for publication, to Editor, *MMWR* Series, Mailstop K-95, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone 888-232-3228.

All material in the *MMWR* Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

All *MMWR* references are available on the Internet at http://www.cdc.gov/mmwr. Use the search function to find specific articles.

Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

References to non-CDC sites on the Internet are provided as a service to *MMWR* readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. CDC is not responsible for the content of these sites. URL addresses listed in *MMWR* were current as of the date of publication.
