## Trends in Childhood Cancer Mortality - United States, 1990-2004

Cancer is the fourth most common cause of death (after unintentional injury, homicide, and suicide) among persons aged 1-19 years in the United States (1,2). Because recent childhood cancer mortality has not been well characterized in terms of temporal, demographic, and geographic trends (2,3), CDC analyzed cancer death rates among children (defined as aged $0-14$ years) and adolescents (defined as aged 15-19 years) for the period 1990-2004 by sex, age group, race, ethnicity, U.S. Census region, and primary cancer site/leading diagnosis, using the most recent data available from the National Vital Statistics System (NVSS). This report describes the results of that analysis, which indicated that, overall, age-adjusted childhood cancer death rates decreased significantly during 1990-2004 among both sexes, both age groups, all races (except American Indians/Alaska Natives [AI/ANs]), Hispanics, non-Hispanics, and all U.S. Census regions. However, decreases in death rates varied among U.S. Census regions and between Hispanics and non-Hispanics. Eliminating racial/ethnic health disparities is one of the overarching goals of Healthy People 2010 (4). Further research is needed to understand geographic and ethnic disparities in childhood cancer death rates. Moreover, cancer prevention and intervention measures should be designed to reach populations that are underserved and at high risk.

NVSS collects death certificate data from vital statistics offices in the 50 states and the District of Columbia.* All reported deaths among children and adolescents during 1990-2004 were included in this analysis. Population estimates used as denominators in death rate calculations were from the U.S. Bureau of the Census and were modified by the Surveillance, Epidemiology, and End Results

[^0](SEER) program (1). ${ }^{\dagger}$ Age-adjusted death rates and trends were calculated for all primary cancer sites combined and for the two leading cancer diagnoses: leukemias and brain and other nervous system neoplasms. ${ }^{\S}$ All rates were per 1 million population and age adjusted to the 2000 U.S. standard population. For all primary cancer sites/leading diagnoses combined, death rates and trends were stratified further by sex, age, race, ethnicity, and U.S. Census region. Rates and overall annual percentage changes (APCs) from 1990 to 2004 were calculated using SEER-Stat. ${ }^{9}$ Joinpoint regression was performed to determine statistically significant changes in trends during 1990-2004 (5). The overall statistical significance level was $\alpha=0.05$, with a maximum of three joinpoints and four line segments allowed (5).
A total of 34,500 childhood cancer deaths were reported in the United States during 1990-2004. A total of 2,223 cancer deaths occurred in 2004; among these, leukemias were the most common diagnoses ( $25.5 \%$ ), followed by brain and other nervous system neoplasms (25.0\%) (Figure 1). From 1990 to 2004, death rates declined

significantly for leukemias by $3.0 \%$ per year, for brain and other nervous system neoplasms by $1.0 \%$ per year, and for all other cancers combined by $1.3 \%$ per year (Table).
For all cancers combined during 1990-2004, boys (33.1 per million) had significantly higher death rates than girls (26.1); adolescents (37.9) had significantly higher death rates than children (26.9); whites (30.1) and blacks (29.3) had significantly higher death rates than Asians/Pacific Islanders (A/PIs) (26.4) and AI/ANs (20.0), respectively; and Hispanics (30.3) had significantly higher death rates than non-Hispanics (29.1) (Table). Death rates decreased similarly by sex, age group, and race; decreases ranged from $1.5 \%$ to $2.0 \%$ per year during 1990-2004. However, APCs, reflecting a decline in death rates, differed by $60 \%$ between Hispanics and non-Hispanics: 1.0\% per year for Hispanics compared with $1.6 \%$ per year for non-Hispanics. Statistical analysis with joinpoint regression revealed that the death rate for whites remained stable during 1990-1992 ( $\mathrm{p}=0.77$ ), declined significantly during 1992-1996 by $4.3 \%$ per year ( $p=0.001$ ), and then stabilized again during 1996-2004 ( $\mathrm{p}=0.07$ ) (Figure 2). Death rates for blacks and A/PIs declined significantly, both by $1.6 \%$ per year ( $p<0.001$ for blacks and $p=0.003$ for A/PIs). Death rates for AI/ANs were stable during 1990-2004 ( $\mathrm{p}=0.18$ ); this trend might be attributed to the small numbers available for

** Northeast: Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont. Midwest: Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin. South: Alabama, Arkansas, Delaware, District of Columbia, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia. West: Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming.
analysis in this population. Regression analysis also revealed that the death rate for Hispanics remained stable during 1990-1992 ( $\mathrm{p}=0.53$ ), declined significantly during 19921998 by $4.3 \%$ per year ( $\mathrm{p}=0.01$ ), and then stabilized during 1998-2001 ( $\mathrm{p}=0.32$ ) and during 2001-2004 ( $p=0.57$ ); the death rate for non-Hispanics declined significantly during $1990-1996$ by $2.6 \%$ per year ( $\mathrm{p}<0.001$ ) and 1996-2004 by $0.9 \%$ per year ( $\mathrm{p}=0.009$ ) (Figure 2).
Death rates did not decrease equally in all regions** during 1990-2004: $2.1 \%$ per year in the Midwest, $1.8 \%$ per year in the South and Northeast, and $1.4 \%$ per year in the

[^3]West (Table). For all cancers combined, children and adolescents living in the West (31.1 per million) had significantly higher death rates than those living in the Midwest (29.1), the Northeast (28.4), and the South (29.8), respectively (Table).
Reported by: LA Pollack, MD, SL Stewart, PhD, TD Thompson, Div of Cancer Prevention and Control, National Center for Chronic Disease Prevention and Health Promotion; J Li, MD, EIS Officer, CDC.
Editorial Note: The findings in this report indicate that, during 1990-2004, overall childhood cancer death rates declined significantly among boys and girls, children and adolescents, Hispanics and non-Hispanics, most racial groups, and all U.S. Census regions. Incidence rates for all childhood cancers increased by $0.6 \%$ per year during 1975-2002 (G). The overall decreasing trend in childhood cancer mortality in the United States likely reflects advances in cancer treatment in this population (3).

FIGURE 2. Rates* of childhood cancer deaths, by race and ethnicity ${ }^{\dagger}$ — United States, 1990-2004

*Per 1 million population; rates age adjusted to the 2000 U.S. standard population.
${ }_{\S} \dagger$ Ethnicity is not mutually exclusive from race categories.
${ }^{\S}$ Death rate remained stable during 1990-1992 ( $p=0.53$ ), declined significantly during 1992-1998 ( $p=0.01$ ), and then stabilized during 1998-2001 ( $p=0.32$ ) and during 2001-2004 $(p=0.57)$.
further studies, including cancer survival studies. Moreover, variations by ethnicity were observed. Hispanics and non-Hispanics had similar childhood cancer death rates in 1990, but these rates declined more rapidly for non-Hispanics than for Hispanics during 1990-2004. Studies have documented that Hispanics lack sufficient access to health-care services because of inadequate heathinsurance coverage, lack of health insurance, poor geographic access to health-care providers, lack of transportation to and from providers, and cultural and linguistic barriers (8), which might contribute to this disparity. However, differences in tumor aggressiveness, cancer stage at diagnosis, and response to treatment also should be considered.
The findings in this report are subject to at least five limitations. First, the reporting of race/ethnicity to the U.S. Bureau of the Census and on death certificates usually is reliable for blacks and whites; however, death rates for American Indians, A/PIs, and Hispanics are underestimated by $21 \%, 11 \%$, and $2 \%$, respectively (9). Second, the ability to stratify death rates for each primary cancer site/leading diagnosis by demographic and geographic variables and to assess the geographic variation at the state or county level was limited because of low death counts. Third, causes of death might be misclassified on death certificates. Fourth, using the 2000 U.S. standard population for all study years might not reflect actual annual population. Finally, cancer deaths among boys and girls who had cancer diagnosed as children but who died as adolescents are reflected in adolescent mortality rates. Thus, the mortality rates of adolescents might reflect the improved survival of children with cancer.
The overall trend of declining childhood cancer mortality during 1990-2004 likely reflects better treatment of childhood cancer. Surveillance of childhood cancer mortality should be well maintained to monitor the persistence of these declines. Possible causes for disparities in childhood cancer death rates (e.g., lack of health insurance, difficulty in accessing health care, late diagnosis, poor treatment quality, and unhealthy behaviors and lifestyles) need to be studied
further. By addressing these factors, geographic and ethnic disparities in childhood cancer death might be reduced, and children with cancer might live longer.
CDC maintains the National Program of Cancer Registries, which monitors cancer rates and trends. CDC also is working in partnership with organizations (e.g., the Lance Armstrong Foundation) to educate childhood cancer survivors, their families, and their health-care providers to recognize long-term effects associated with cancer treatment. These measures aim to enhance quality of life and increase survival.

## Surveillance for Travel-Associated Legionnaires Disease United States, 2005-2006

An estimated 8,000-18,000 persons are hospitalized with Legionnaires disease (LD) each year in the United States (1), and approximately 20\% of reported LD cases are associated with travel (2). Outbreaks of travelassociated LD can be difficult to detect because travelers disperse and Legionella-specific diagnostic tests are underutilized (3). Consequently, clinicians and health departments often are unaware when more than one LD case is associated with a common travel destination. In 2005, the Council of State and Territorial Epidemiologists
(CSTE) adopted a position statement recommending enhanced surveillance measures for LD, with emphasis on diagnosis and reporting of confirmed travel-associated LD cases within 7 days.* The rationale for enhanced surveillance was that earlier detection might lead to more rapid identification of a source (e.g., cooling tower) and expedite prevention measures (e.g., cleaning and chlorination). To 1) assess data from 32 states that used a supplementary reporting system for LD, 2) describe the epidemiology of travel-associated LD, and 3) compare characteristics of travel-associated cases with those of cases not associated with travel, CDC analyzed LD cases reported via the supplementary system during 2005-2006. The results of that analysis indicated that the proportion of LD cases that were travel associated remained stable from 2005 ( $23 \%$ ) to 2006 ( $25 \%$ ), the proportion of travel-associated cases reported via a dedicated CDC e-mail address increased from $11 \%$ to $24 \%$, and the number of reported clusters of travelassociated LD increased from two in 2005 to eight in 2006. These results suggest that, to fully assess the benefits of enhanced LD surveillance, more states will need to adopt the CSTE recommendations.
LD cases are reported to CDC through the National Notifiable Diseases Surveillance System (NNDSS); this system collects certain patient demographic information (e.g., age and state of residence) but not travel history. Since 1980, states have had the option of additionally reporting more detailed information voluntarily to CDC through a supplementary LD reporting system, using a paper caseLD report form ${ }^{\dagger}$ that defines confirmed cases of LD and collects information related to diagnostic testing, location of disease acquisition (i.e., community or hospital), and travel. For this analysis, only confirmed LD cases were included. In 2005 and 2006, totals of 2,301 and 2,834 cases of LD, respectively, were reported to NNDSS, of which 603 (26\%) and 729 (26\%) cases, respectively, also were reported via the supplementary system (4,5). During 2005-2006, LD cases were reported through the supplementary system by 32 states; five states (Ohio, Michigan, New Jersey, New York, and Virginia) submitted the majority ( $69 \%$ ) of supplementary reports. A case of LD was considered to be travel associated if the patient reported spending at least one night away from home during the 2 weeks ${ }^{\S}$ before illness onset; possible nosocomial cases were

[^4]excluded. Changes in data from 2005 to 2006 were determined to be statistically significant at $\mathrm{p}<0.05$ by chi-square test.
The proportions of LD cases that were travel associated and reported via the supplementary system were similar in 2005 ( 136 of 603 [ $23 \%]$ ) and 2006 ( 183 of 729 [25\%]). Reporting via the dedicated CDC e-mail address (travellegionella@cdc.gov), which can facilitate timely reporting, increased significantly, from 15 reports ( $11 \%$ ) in 2005 to 44 reports ( $24 \%$ ) in 2006 (Table 1). The supplementary system recorded two clusters (defined as two or more cases associated with the same potential source during a 12 -month period) of travel-associated LD in 2005 and eight clusters in 2006. Of these 10 clusters overall, seven were associated with hotels, and three were associated with cruise ships; each cluster consisted of either two or three cases of LD. The majority of persons with travelassociated LD had traveled to destinations outside their state of residence.
During 2005-2006, the median age was 59 years for persons with travel-associated LD and 60 years for non-travel-associated LD (Table 2). Among those with

${ }_{\S}^{\dagger}$ Denominators vary because certain data were not available.
$\S_{\text {More than one type of test might apply. }}$
travel-associated LD, $74 \%$ were male, and $88 \%$ were white. Among the 252 patients with travel-associated LD and known outcome, 15 ( $6 \%$ ) died, compared with 71 ( $8 \%$ ) of the 882 patients with non-travel-associated LD. Approximately $96 \%$ of both travel-associated and non-travel-associated LD cases were diagnosed by urine antigen testing; few were diagnosed by Legionella culture or serology. Reported by: P Smith, MD, Div of Epidemiology, New York State Health Dept. M Moore, MD, NAlexander, MPH, L Hicks, DO, Div of Bacterial Diseases, National Center for Immunization and Respiratory Diseases; R O'Loughlin, PhD, EIS Officer, CDC.
Editorial Note: The 2,301 LD cases reported to NNDSS in 2005 and the 2,834 cases reported in 2006 represent only a fraction of the estimated $8,000-18,000$ cases of LD that require hospitalization each year in the United States (1), likely because of underdiagnosis and underreporting. The 2005 CSTE position statement recommended that all cases of LD be reported to CDC to enhance recognition of outbreaks and enable earlier implementation of prevention measures. CSTE also set parameters for timely reporting of travel-associated LD cases, recommending that investigating health departments ascertain whether cases are travel associated and report them to CDC within 7 days of notification of a case. CDC encourages states to submit casereport forms for all LD cases; non-travel-associated cases should be reported to CDC within 30 days. Although the CSTE position statement was not adopted until June 2005, increased use of dedicated e-mail for reporting and improved
identification of clusters was noted in 2006 for travelassociated LD.
The proportion of LD cases diagnosed by culture has declined since introduction of urine antigen testing (2), and tests are performed on only a limited proportion of patients who have indications for urine antigen testing or Legionella culture of respiratory specimens (6). Despite the convenience of urine antigen testing, the availability of a clinical isolate of Legionella improves the likelihood that an environmental source for Legionella can be identified (i.e., by matching the characteristics of clinical and environmental isolates) and remediated $(7,8)$. In addition, CDC recently implemented DNA sequence-based typing to compare individual clinical strains of Legionella among travelers. Strain typing has contributed to identification of clusters of travel-associated LD in Europe (9) and might provide similar benefits in the United States. Therefore, CDC is requesting that state health departments forward to CDC all clinical isolates of Legionella obtained from persons who report that they traveled during the 2-14 days before onset of illness. Details regarding the isolate submission process can be obtained by e-mail (travellegionella@cdc.gov) or by telephone (404-6390418).

The findings in this report are subject to at least five limitations. First, because analysis was limited to 20052006 and the CSTE position statement was adopted in 2005, sufficient time might not have elapsed to attribute changes in LD reporting to the CSTE statement. Second, the data presented likely underestimate the number of cases of LD because diagnostic tests for LD are underutilized in the United States. Utilization might increase as more clinicians follow recently updated guidelines for management of community-acquired pneumonia, including LD (10). Third, travel-associated LD cases might be underestimated because not all clinicians obtain a travel history from all patients with community-acquired pneumonia. Fourth, although an increase in reporting by e-mail might suggest more rapid reporting, timeliness of reporting could not be assessed because the dates that reports were received by CDC were not recorded. Finally, although all states are required to report LD to NNDSS, only $26 \%$ of these LD cases also were reported via the voluntary supplementary system during 2005-2006. Therefore, the detailed data provided on case-report forms might not be representative of all reported LD cases.
Identification of a single case of LD suggests the possibility of an environmental source to which other persons might be exposed. Therefore, timely reporting all cases of travel-associated LD to CDC is important for identifying
clusters. CDC encourages state health departments to post information on LD cases associated with travel on the CDC Epidemic Information Exchange (Epi-X) to alert other health officials to review their records for cases of LD associated with travel to the same destination. During 20052006, a total of 30 Epi-X postings asked that cases of LD associated with travel to specific locations be reported to CDC or to the investigating state health department. CDC resources for investigating and reporting cases of travelassociated LD are available at http://www.cdc.gov/ legionella. CDC also continues to be available for consultation with regard to LD clusters.

## Brief Report

## Respiratory Syncytial Virus Activity United States, July 2006-November 2007

Respiratory syncytial virus (RSV), the most common cause of severe lower respiratory tract disease among infants and young children, typically infects persons by age 2 years and can cause subsequent infections throughout life (1). RSV infection primarily manifests as bronchiolitis or pneumonia and results in approximately 75,000 to 125,000 hospitalizations in the United States each year (1). Persons
at increased risk for severe disease or death include premature infants, older adults, and persons of any age with compromised respiratory, cardiac, or immune systems $(2,3)$. RSV is transmitted from person to person via close contact, droplets, or fomites. In temperate climates, peak RSV activity typically occurs during the winter. However, year-to-year national and regional variability in the RSV season onset and offset* occurs in the United States (4). RSV circulation also varies by geographic location; for example, Florida has an earlier season onset and a longer season than the rest of the United States (5). Using data reported to the National Respiratory and Enteric Virus Surveillance System (NREVSS), this report summarizes RSV temporal and geographic trends in the United States during the weeks ending July 8, 2006-June 30, 2007, and for the first 5 months of the current reporting season (the weeks ending July 7-November 24, 2007). Appropriately timed diagnostic tests can provide data that indicate when the RSV season begins nationally and regionally, information that has been critical in determining when to begin RSV prophylaxis for infants and children at high risk for infection.
NREVSS receives weekly reports from a passive voluntary network of laboratories regarding the number of specimens tested for specific viral pathogens, including RSV, and the number of positive results, stratified by test type. During July 2006-June 2007, a total of 94 clinical and public health laboratories reported RSV data. Laboratories that were included in this analysis met the following three criteria: reported $\geq 30$ weeks of data, tested $\geq 15$ specimens per week during the winter months, and reported $\geq 2 \%$ of specimens testing positive annually. Sixty-three ( $67 \%$ ) laboratories representing 36 states met these criteria and reported a total of 126,617 RSV antigen-detection tests, of which $21,470(17.0 \%)$ were positive. The national RSV season onset began during the week ending November 11, 2006, and continued for 19 weeks until the season offset (week ending March 17, 2007).
Data were summarized by region ${ }^{\dagger}$ (Midwest, South [excluding Florida], Northeast, and West); data from Florida are presented separately because they differed substantially

[^5]from RSV-detection data from the remainder of the South (5) (Figure). The 2006-07 RSV season onset occurred during the week ending November 11, 2006, in the Midwest (12 laboratories reporting); the week ending November 18 in the Northeast (eight laboratories reporting); and the week ending December 16 in the West ( 14 laboratories reporting). The season offset occurred during the week ending February 10, 2007, in the Northeast; the week ending March 17 in the Midwest; and the week ending March 31 in the West. The RSV season onset in the South (excluding Florida) (27 laboratories reporting) began during the week ending October 28, 2006, and continued until the week ending February 24, 2007 ( 18 weeks). The RSV season onset in Florida (two Miami laboratories reporting) began during the week ending July 1, 2006, and continued until the week ending January 27, 2007 (31 weeks).
For the 2007-08 season, the number of reporting laboratories and geographic coverage has increased substantially as a result of a data-sharing agreement with Surveillance Data, Inc. (SDI), a private company that conducts RSV surveillance. ${ }^{\S}$ On the basis of preliminary reports from the week ending July 7, 2007, to the week ending November 24, a total of 179 laboratories in 46 states and the District of Columbia reported 69,230 RSV tests and 5,173 (7.5\%) positive results by antigen detection to NREVSS. Reports received through November 24 indicate that although the national RSV season onset has not yet occurred, the regional season onset occurred during the week ending November 17 in the South ( 58 laboratories reporting, excluding Florida) and during the week ending November 24 in the Northeast ( 23 laboratories reporting). As of November 24, reports from the Midwest (48 laboratories reporting) and West (37 laboratories reporting) did not indicate onset of the RSV season. Florida continued to have a unique onset (week ending August 4 [13 laboratories reporting]). Weekly updates indicating RSV national, regional, and state trends are available from the NREVSS website ( $)$ ); data from Florida laboratories are available from the Florida Department of Public health website (7).
No vaccine or effective therapy is available for RSV. Infants and children at risk for severe RSV infection can

[^6]FIGURE. Percentage of specimens testing positive for respiratory syncytial virus (RSV) antigen, by region* and week of report United States, July 8, 2006-November 24, 2007

* Northeast: Connecticut, Massachusetts, New Hampshire, New Jersey, New York, and Rhode Island; Midwest: Illinois, Indiana, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin; South: Alabama, Arkansas, Delaware, District of Columbia, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, and Virginia; West: Alaska, Arizona, California, Colorado, Hawaii, Montana, Washington, and Wyoming; Florida. (Data from Florida are presented separately because they differed substantially from RSV-detection data from the remainder of the South region.)
receive immune prophylaxis with monthly doses of a humanized murine anti-RSV monoclonal antibody during the RSV season (8). Specific immune prophylaxis guidelines are available from the American Academy of Pediatrics (8,9).
Reported by: National Respiratory and Enteric Virus Surveillance System collaborating laboratories. CA Panozzo, MPH, AL Fowlkes, MPH, E Schneider, MD, LJ Anderson, MD, Div of Viral Diseases, National Center for Immunization and Respiratory Diseases, $C D C$.

## Notice to Readers

## Recommendation from the Advisory Committee on Immunization Practices (ACIP) for Use of Quadrivalent Meningococcal Conjugate Vaccine (MCV4) in Children Aged 2-10 Years at Increased Risk for Invasive Meningococcal Disease

On October 17, 2007, the Food and Drug Administration approved quadrivalent meningococcal conjugate vaccine (MCV4) (Menactra ${ }^{\circledR}$, Sanofi Pasteur, Swiftwater,

Pennsylvania) for use in children aged 2-10 years, in addition to its prior approval for use in persons aged 11-55 years (1). Previous Advisory Committee on Immunization Practices (ACIP) recommendations called for routine vaccination with meningococcal polysaccharide vaccine (MPSV4) (Menomune ${ }^{\circledR}$, Sanofi Pasteur) of children aged $2-10$ years who are at increased risk for meningococcal disease. These children include travelers to or residents of countries in which meningococcal disease is hyperendemic or epidemic, children who have terminal complement component deficiencies, and children who have anatomic or functional asplenia (2). This notice provides updated recommendations for meningococcal vaccination among children aged 2-10 years at increased risk for meningococcal disease.

In anticipation of possible licensure of MCV4 for children aged 2-10 years, during February 2007-October 2007, the ACIP meningococcal vaccine workgroup reviewed data on MCV4 immunogenicity and safety in children in that age group. On the basis of these data, opinions of workgroup members, and feedback from partner organizations, the workgroup proposed recommendations for use of MCV4 among children aged 2-10 years who are at increased risk for meningococcal disease. The recommendations were approved by ACIP at its October 24, 2007, meeting.
In a single, randomized, modified double-blind, controlled study of healthy U.S. children aged $2-10$ years that compared MCV4 with MPSV4, serum bactericidal antibody geometric mean titers against all four serogroups were significantly higher at both 28 days and 6 months after vaccination in the children who received MCV4 (3). In the same study, rates of most solicited local and systemic adverse events after vaccination with MCV4 were comparable to rates observed after vaccination with MPSV4 (3). Although duration of protective immunity from MCV4 is not yet known, conjugate vaccines generally have a longer duration of protection than polysaccharide vaccines (2).
At its October meeting, ACIP revised its recommendation to state that MCV4 is preferable to MPSV4 for vaccination of children aged $2-10$ years who are at increased risk for meningococcal disease. These children include travelers to or residents of countries in which meningococcal disease is hyperendemic or epidemic, children who have terminal complement component deficiencies, and children who have anatomic or functional asplenia (2). Additionally, MCV4 is preferred to MPSV4 for use among children aged 2-10 years for control of meningococcal disease outbreaks. Providers may elect to vaccinate children aged 210 years who are infected with human immunodeficiency
virus (HIV).* For children aged 2-10 years who have previously received MPSV4 and remain at increased risk for meningococcal disease, ACIP recommends vaccination with MCV4 at 3 years after receipt of MPSV4. Children who last received MPSV4 more than 3 years ago and remain at risk for meningococcal disease should be vaccinated with MCV4 as soon as possible. For children at lifelong increased risk for meningococcal disease, subsequent doses of MCV4 likely will be needed. ACIP will make recommendations for revaccination with MCV4 as more data on duration of protection become available.
Persons with a history of Guillain-Barré syndrome (GBS) might be at increased risk for GBS after MCV4 vaccination (4); therefore, a history of GBS is a precaution (5) to administering MCV4. For children with a history of GBS, MPSV4 is an acceptable alternative for short-term (i.e., $3-5$ years) protection against meningococcal disease.
The ACIP meningococcal vaccine workgroup is considering options for general use of MCV4 among children aged $2-10$ years. Recommendations will be presented at a future ACIP meeting. Recommendations for use of MCV4 in persons aged $11-55$ years, including a recommendation for routine vaccination with MCV4 of persons aged 11-18 years, have been published previously and remain unchanged (3,6).

## Epidemiology in Action: Intermediate Analytic Methods Course

CDC and Emory University's Rollins School of Public Health will cosponsor the course Epidemiology in Action: Intermediate Analytic Methods on February 25-29, 2008, at Emory University, Rollins School of Public Health. The course is designed for practicing public health professionals who have had training and experience in basic applied epidemiology and would like training in additional quantitative skills related to analysis and interpretation of epidemiologic data. The course includes a review of the fundamentals of descriptive epidemiology and biostatistics, measures of association, normal and binomial distributions, confounding, statistical tests, stratification, logistic regression models, and computer programs used in epidemiology.

The prerequisite is an introductory course in epidemiology, such as Epidemiology in Action or the International Course in Applied Epidemiology. Tuition is charged. The application deadline is January 26, 2008, or when all slots have been filled.

Additional information and applications are available from Emory University, Hubert Global Health Dept (Attn: Pia), 1518 Clifton Rd. NE, Rm. 746, Atlanta, GA 30322; or by telephone, 404-727-3485; fax, 404-727-4590; website, http://www.sph.emory.edu/epicourses; or e-mail, pvaleri@sph.emory.edu.

## Errata: Vol. 54, No. RR-16

In the MMWR Recommendations and Reports, "A Comprehensive Immunization Strategy to Eliminate Transmission of Hepatitis B Virus Infection in the United States:

Recommendations of the Advisory Committee on Immunization Practices (ACIP) - Part 1: Immunization of Infants, Children, and Adolescents," the following errors occurred:

On page 8, in Table 2, in the first row, "Infants ( $<1 \mathrm{yr}$ )," under the column heading "Combination vaccine, Pediarix, Dose ( $\mu \mathrm{g}$ )," the text should read, "10."

On page 9, in Table 4, under the column heading "Recommendation," the second bullet should read, "Administer 3 additional hepatitis B vaccine doses with single-antigen vaccine at ages $1,2-3$, and 6 mos or hepatitis B-containing combination vaccine at ages 2, 4, and 6 mos (Pediarix) or 2, 4, and $12-15 \operatorname{mos}(C o m v a x) .{ }^{\dagger "}$

The fourth bullet should read, "Test for HBsAg and antibody to HBsAg $1-2$ mos after completion of $\geq 3$ doses of a licensed hepatitis B vaccine series (i.e., at age 9-18 mos, generally at the next well-child visit). Testing should not be performed before age 9 mos nor within 4 wks of the most recent vaccine dose."

The seventh bullet should read, "Administer 3 additional hepatitis B vaccine doses with single-antigen vaccine at ages $1,2-3$, and 6 mos or hepatitis B-containing combination vaccine at ages 2,4 , and 6 mos (Pediarix) or 2, 4, and 12-15 mos (Comvax). ${ }^{\dagger "}$

The 10th bullet should read, "Complete the hepatitis B vaccine series with single-antigen vaccine at ages 2 mos and $6-18$ mos or hepatitis B-containing combination vaccine at ages 2, 4, and 6 mos (Pediarix) or 2, 4, and 12-15 mos (Comvax). ${ }^{\dagger "}$

The following footnote should be added to Table 4: "†The final dose in the vaccine series should not be administered before age 24 weeks (164 days)."

The corrected Table 4 is available in its entirety at http:// www.cdc.gov/hepatitis/hbv/pdfs/correctedtable4.pdf.

TABLE I. Provisional cases of infrequently reported notifiable diseases ( $<1,000$ cases reported during the preceding year) - United States, week ending December 1, 2007 (48th Week)*

[^8]* Incidence data for reporting year 2007 are provisional, whereas data for 2002, 2003, 2004, 2005, and 2006 are finalized.
$\dagger$ Calculated by summing the incidence counts for the current week, the 2 weeks preceding the current week, and the 2 weeks following the current week, for a total of 5 preceding years. Additional information is available at http://www.cdc.gov/epo/dphsi/phs/files/5yearweeklyaverage.pdf.
§ Not notifiable in all states. Data from states where the condition is not notifiable are excluded from this table, except in 2007 for the domestic arboviral diseases and influenzaassociated pediatric mortality, and in 2003 for SARS-CoV. Reporting exceptions are available at http://www.cdc.gov/epo/dphsi/phs/infdis.htm.
II Includes both neuroinvasive and nonneuroinvasive. Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, VectorBorne, and Enteric Diseases (ArboNET Surveillance). Data for West Nile virus are available in Table II.
** Data for H. influenzae (all ages, all serotypes) are available in Table II
$\dagger \dagger$ Updated monthly from reports to the Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention. Implementation of HIV reporting influences the number of cases reported. Updates of pediatric HIV data have been temporarily suspended until upgrading of the national HIV/AIDS surveillance data management system is completed. Data for HIV/AIDS, when available, are displayed in Table IV, which appears quarterly.
§§ Updated weekly from reports to the Influenza Division, National Center for Immunization and Respiratory Diseases. One case occurring during the 2007-08 influenza season has been reported. A total of 73 cases were reported for the 2006-07 influenza season
IIf $N o$ measles cases were reported for the current week.
*** Data for meningococcal disease (all serogroups) are available in Table II
${ }^{\dagger \dagger \dagger}$ The one rubella case reported for the current week was unknown.
Uss Updated weekly from reports to the Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases

TABLE II. Provisional cases of selected notifiable diseases, United States, weeks ending December 1, 2007, and December 2, 2006 (48th Week)*

[^9]U: Unavailable. -: No reported cases. N: Not notifiable. Cum: Cumulative year-to-date counts. Med: Median. Max: Maximum.

* Incidence data for reporting year 2007 are provisional. Data for HIV/AIDS, AIDS, and TB, when available, are displayed in Table IV, which appears quarterly.

Chlamydia refers to genital infections caused by Chlamydia trachomatis.
${ }^{\text {§ }}$ Contains data reported through the National Electronic Disease Surveillance System (NEDSS).

[^10]U: Unavailable. -: No reported cases. N: Not notifiable. Cum: Cumulative year-to-date counts. Med: Median. Max: Maximum.

* Incidence data for reporting year 2007 are provisional.
${ }_{\S}^{\dagger}$ Includes E. coli O157:H7; Shiga toxin-positive, serogroup non-O157; and Shiga toxin-positive, not serogrouped.
${ }^{\S}$ Contains data reported through the National Electronic Disease Surveillance System (NEDSS).

TABLE II. (Continued) Provisional cases of selected notifiable diseases, United States, weeks ending December 1, 2007, and December 2, 2006 (48th Week)*

C.N.M.I.: Commonwealth of Northern Mariana Islands.

U: Unavailable. -: No reported cases. N: Not notifiable. Cum: Cumulative year-to-date counts. Med: Median. Max: Maximum.
${ }^{*}$ Incidence data for reporting year 2007 are provisional.
$\dagger$ Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (ArboNET Surveillance). Data § for California serogroup, eastern equine, Powassan, St. Louis, and western equine diseases are available in Table I.
${ }^{\S}$ Not notifiable in all states. Data from states where the condition is not notifiable are excluded from this table, except in 2007 for the domestic arboviral diseases and influenzaIf associated pediatric mortality, and in 2003 for SARS-CoV. Reporting exceptions are available at http://www.cdc.gov/epo/dphsi/phs/infdis.htm.
Contains data reported through the National Electronic Disease Surveillance System (NEDSS).

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format. To receive an electronic copy each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read SUBscribe mmwr$t o c$. Electronic copy also is available from CDC's Internet server at http://www.cdc.gov/mmwr or from CDC's file transfer protocol server at ftp://ftp.cdc.gov/pub/ publications/mmwr. Paper copy subscriptions are available through the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone 202-512-1800.

Data in the weekly $M M W R$ are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Data are compiled in the National Center for Public Health Informatics, Division of Integrated Surveillance Systems and Services. Address all inquiries about the MMWR Series, including material to be considered for publication, to Editor, MMWR Series, Mailstop E-90, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333 or to www.mmwrq@cdc.gov.

All material in the $M M W R$ Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.
Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.
References to non-CDC sites on the Internet are provided as a service to $M M W R$ readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. CDC is not responsible for the content of these sites. URL addresses listed in $M M W R$ were current as of the date of publication.

    ${ }^{\dagger}$ Available at http://www.cdc.gov/legionella/files/legionella_case_report.pdf.
    ${ }^{\$}$ The 2005 CSTE position statement was used to define confirmed cases of travelassociated LD, with the following exception: LD cases were considered travel associated if patients had a history of travel in the 2 weeks, rather than 10 days, before onset of illness.

[^5]:    *As defined by NREVSS, RSV national and regional season onset is the first of 2 consecutive weeks during which the median percentage of specimens testing positive for RSV antigen is $\geq 10 \%$. RSV season offset is the last of 2 consecutive weeks during which the median percentage of positive specimens is $\geq 10 \%$.
    ${ }^{\dagger}$ Northeast: Connecticut, Massachusetts, New Hampshire, New Jersey, New York, and Rhode Island; Midwest: Illinois, Indiana, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin; South: Alabama, Arkansas, Delaware, District of Columbia, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, and Virginia; West: Alaska, Arizona, California, Colorado, Hawaii, Montana, Washington, and Wyoming; Florida.

[^6]:    \$ SDI conducts RSV surveillance with support from MedImmune, Inc. (Gaithersburg, Maryland). In fall 2006, CDC and SDI signed a memorandum of understanding to share RSV surveillance data to make the most complete RSV dataset available. The memorandum outlines the voluntary participation of laboratories, type of data shared, frequency of reporting, and approval and acknowledgements for data publication. The relationship between CDC and SDI is limited to data sharing, as outlined in the memorandum. CDC does not make recommendations regarding the administration of RSV immune prophylaxis. For additional information, contact NREVSS by e-mail at nrevss@cdc.gov.

[^7]:    *Children with HIV infection likely are at increased risk for meningococcal disease, although not to the extent that they are at risk for invasive Streptococcusp peumoniae infection. The efficacy of MCV4 among HIV-infected children is unknown.

[^8]:    -: No reported cases. N: Not notifiable. Cum: Cumulative year-to-date counts

[^9]:    C.N.M.I.: Commonwealth of Northern Mariana Islands

[^10]:    C.N.M.I.: Commonwealth of Northern Mariana Islands.

[^11]:    C.N.M.I.: Commonwealth of Northern Mariana Islands.

    U: Unavailable. -: No reported cases. N: Not notifiable. Cum: Cumulative year-to-date counts. Med: Median. Max: Maximum.

    * Incidence data for reporting year 2007 are provisional.
    $\dagger$ Includes cases of invasive pneumococcal disease, in children aged $<5$ years, caused by S. pneumoniae, which is susceptible or for which susceptibility testing is not available (NNDSS event code 11717).
    §ontains data reported through the National Electronic Disease Surveillance System (NEDSS).

[^12]:    U: Unavailable. -:No reported cases.

    * Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of $\geq 100,000$. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
    $\dagger$ Pneumonia and influenza.
    § Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
    ${ }^{\text {® }}$ Because of Hurricane Katrina, weekly reporting of deaths has been temporarily disrupted.
    **Total includes unknown ages.
